One of the common features of all presentation recording systems is the capture of the instructor's verbal narration. It is quite obvious that without this, an essential and substantial part of the information will be missing. In addition, all presentation recording systems include the presented slides in the recorded documents. The major goals are to capture as many of the relevant media streams as possible, to preserve

602

the live character of a presentation, and to provide a comfortable navigation within (and in between) recorded documents. This also means that a tightly synchronous replay of all media streams must be possible regardless of the machine used to play back the recording. Simply capturing starting times of events (such as launching an application) can result in streams drifting apart, depending on the performance of the replay machine.

All of the recording should be done with the highest possible degree of automation and the lowest possible degree of obtrusiveness. Note that most presentation and recording systems require the instructor to directly interact with the computer during the lecture. One of the challenges to be solved in general is how the user interface for the lecturer can be designed such that it deviates as little as possible from the traditional blackboard-and-chalk paradigm.

The following criteria illustrate the differences between particular software approaches to presentation recording, leaving out all the hardware aspects that might be involved. While we do not claim our list to be complete, it contains the features which we consider most important, judging from our experience of using presentation recording in a university environment (see Datta & Ottmann 2001). We will also mention systems which provide a good sample of each particular criterion listed.

Representation of Contents

Simply videotaping lectures does not only lead to unacceptable quality of the filmed blackboard or slides. Even if this shortcoming might be improved with better technology, standard video formats have one additional major drawback: the information is not represented symbolically but as a series of bitmaps over time. Thus, it will involve tremendous effort to retrieve information from such a recording and to allow, for instance, full-text search within a lecture document.

It is therefore desirable to preserve all symbolic information of the original contents wherever possible. Apart from searchability, this representation yields some more advantages. First, text and vector graphics can be scaled without loss in quality to fit different screen resolutions on replay machines, while bitmap images will always suffer when enlarged or scaled down from their original size. Second, symbolic representation facilitates later manipulation of contents, for example, to remove errors or change attributes of objects. And third, it is also likely to reduce the amount of data compared to video formats.

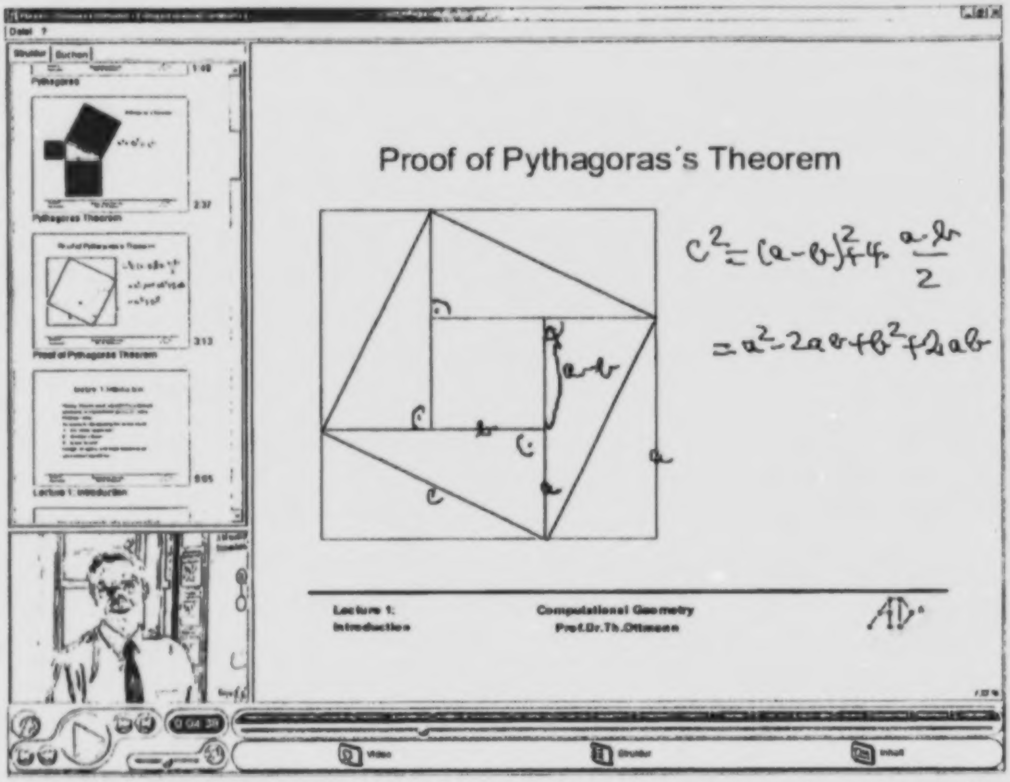
Very few of the recording systems known to us preserve the symbolic representation. Of these, Lecturnity is the only one that also provides an integrated full-text search to find slides containing search strings.

Dynamic Capture and Replay of Annotations

In the educational domain of the natural sciences but also many others, instructors do not confine themselves to the presentation of pre-produced material. Rather, they will annotate the slides presented or even start from a completely empty page (or blackboard) and gradually develop complicated lines of thought using handwriting and graphical objects. In computer-assisted presentations, some dynamics may be introduced through animations provided by commercial presentation systems (such as MS-PowerPoint). The possibility of handwritten annotations, however, allows for much more flexibility; examples include answering student questions, addressing new aspects, detailing a mathematical proof (see Fig.1), and many more. It is one important requirement that it should be possible to dynamically record handwritten annotations such that they can be replayed synchronously with the verbal narration.

Of course handwritten annotation requires suitable hardware. Currently we are still far away from input devices providing the look and feel of traditional blackboards and chalk. Fortunately, new input devices such as electronic whiteboards or pen-sensitive displays have somewhat improved the situation.

Although PowerPoint itself allows free-hand annotation on the slides, the recording plug-ins we know of, surprisingly, do not capture those annotations at all. Desktop grabbing tools naturally record all the dynamics on the screen or, like Camtasia, even offer their own annotation feature. One significant disadvantage of such a solution, however, is that the notes have to be erased manually since the recording tool does not "know" when a new slide or application is being shown. In systems like AOF, eClass or Lecturnity, where annotations are associated with the slide on which they were made, all notes will automatically disappear when the slide is changed and be visible again when returning to that slide later in the presentation.



Proof of Pythagoras's Theorem

$$c^2 = (a-b)^2 + 4\cdot\frac{a\cdot b}{2}$$

$$= a^2 - 2ab + b^2 + 2ab$$

Figure 1: Replay of a lecture recorded with Lectumity, featuring a thumbnail overview, a video or still picture of the instructor, the content frame with slides and annotations, and a navigation unit.

Structured Overview of Recordings

Comfortable navigation within the recorded documents must be one major goal. An overview or table of contents showing the structure of the captured session is an important method to facilitate navigation (Brusilovsky 2000). One way of implementing this can be thumbnails of the individual slides with links to the respective parts of the recording. Of course, such an overview should be generated automatically if possible. However, automatic structuring can only be achieved if the recording mechanism has some information about the presented contents, such as the timing of slide changes. A conventional screen recording tool does not have this information. The TeleTeachingTool tries to overcome this problem by identifying major changes in the captured images (which are likely to reflect slide changes), thus allowing the user to jump to the next slide. The video-based system in (Dal Lago et al. 2002) extracts slide titles to automatically index a video stream, but depends on the use of PowerPoint slides.
An automatically created, fully linked thumbnail overview is provided by AOF and Lecturnity (Fig. 1), which even supports different image sizes for the thumbnails.

Visible Scrolling During Replay

Another feature enhancing navigational comfort is fast visible scrolling, which allows students to browse through a recorded presentation by dragging a slider along a scrollbar. Of course, for this scenario to be user-friendly, the frame updates must display instantly during scrolling without a noticeable delay. In order to achieve this kind of navigation (which is similar to skimming through a book), the document format

BEST COPY AVAILABLE

must support real-time random access. Note that if continuous media are delivered via a streaming server they cannot at the same time provide fast visible scrolling. This is because only a small part of the document is buffered locally at any given time. In order to make random access work in real time, the document as a whole must be stored locally.

Examples for systems supporting visible scrolling include AOF, Lecturnity, and some video formats if replayed locally (i.e., not streamed) using a suitable player.

File Format and Size of Recorded Documents

As mentioned above, if recordings are delivered to the end user via a streaming server, the feature of visible scrolling cannot be supported at the same time. On the other hand, if the files are to be downloaded by the students, file size should not be neglected, even though the increasing availability of broadband connections is likely to make this a minor problem in the future.

It is, of course, desirable that the recordings have a platform-independent format, or even better, a standard "web-based" format (such as HTML, Flash, MPEG, RealMedia, etc.). That way, users will not have to install additional software on their computers, as most operating systems or web browsers will be ready to replay the documents. On the other hand, many of those formats do not support real-time random access which is necessary for visible scrolling, and therefore lack an important navigational feature.

Producing a video from a computer presentation by screen grabbing, i.e. by taking a series of, say 10 screen shots per second and compressing the resulting movie using the standard video codecs of the MPEG family does in most cases neither lead to acceptable quality nor to a reasonable size of the compressed file. Special lossless codecs are required to compress this kind of video (Deshpande & Hwang 2001).

Camtasia offers a great variety of formats for the export of grabbed videos and, with TSCC, provides a very powerful lossless codec particularly suited for videos resulting from recorded screen contents.

Formats of Materials Which Can Be Captured

The ultimate goal of presentation recording is to record all relevant media streams occurring in the live session. This includes the support of any given file format or application used by the instructor. Tools recording desktop contents, like Camtasia, can capture virtually any material displayed on the screen.

However, there will always be a trade-off between the number of usable raw formats and other features. For example, in order to automatically create a fully linked table of contents, the recording tool has to "know" the materials in the sense that slide changes, annotations, or calls of external applications all have to be done from within (or at least be recognized by) the recording system. A tool which simply grabs screen or window contents, although it can capture virtually any material displayed on the screen, will not be able to automatically generate a structured overview of a recording.

Capture and Integration of Live Video

A video picture of the instructor provides a visual impression as well as a feeling of the instructor's "presence." On the other hand, in relation to the amount of data video usually conveys very little information, except if showing objects or experiments relevant to the subject discussed in the course. The importance of integrating live video should therefore not be overestimated. A static image of the instructor will often be sufficient and reduce the amount of data drastically.

If live video is to be included, the process should be automated and involve as little manual work as possible. In this respect, the PowerPoint add-ons RealPresenter or Microsoft Producer are among the most comfortable tools.

Post-Editing Facilities

Whether or not recorded presentations can or should be post-edited is not only a matter of available resources but also of personal taste and perfectionism. In order to preserve the live character of a presentation, it might even be the best thing to avoid later changes completely. Nevertheless, some facility for post-editing the recordings is definitely a useful tool.

There are quite a number of editing tools available which make it easy to cut and join parts of different recordings if they are in a video format. However, as mentioned above, the contents of slides can best be manipulated if they are represented symbolically. For example, erroneous text on a slide may hardly be corrected later if the recording is in a video format, while there will be no problem if it is still represented as a text object. However, one might have to edit large files "by hand," since none of the systems featuring symbolic representation offers a user-friendly editor. Among the other tools, Camtasia probably offers the most comfortable solution for cutting and joining recordings.

Turning Recordings into a CD-ROM or Web-Based Course

In order to really make use of the recordings as parts of integrated e-learning modules, there should be an easy way to combine the documents with exercises and other materials and to organize the courses in a web-based learning management system or on distributable storage media like CD-ROM or DVD. Automated processes, interfaces, or metadata are possible methods for facilitating such an integration. Furthermore, the random access capability can provide a convenient way to link presentation recordings to other web-based material.

AOF with its open format can easily be post-processed by batch scripts. Lecturnity and PresenterONE prompt the user to enter metadata such as author, keywords etc. for each recording and also include tools for publishing collections of captured talks on the web or CD-ROM.

	Symbolic representation	Dynamic capture of annotations	Structured overview	Visible scrolling	Standard format for replay	Supported input formats	Live video	Post-editing	Creation of web-based courses
AOF	✓	✓	✓	✓	optional conversion to Real[1) 9)]	ppt[2)], gif, png, jpg, ps[3)]	✓[4)]	✓[5)]	Scripts, metadata
Camtasia	---	✓	---	✓[6)]	avi, wmv, asf, mov, Real etc.	any (screen recording)	✓	✓	---
eClass	—[14)]	✓[15)]	✓	---	HTML, RealMedia	gif, jpg, HTML	✓	—	✓
IMoD	✓	✓[12)]	✓	—	—[7)]	multi[8)]	✓	---	Tools for creating CBTs
Lecturnity	✓	✓	✓	✓	optional conversion to Real[9)]	ppt[2)], gif, jpg, png	✓[4)]	—	Metadata, publishing assistant
MS Producer	✓	—	✓	—	extended HTML (IE5 only)	ppt[10)]	✓	✓	✓
PresenterONE	—[14)]	—	✓	—	RealMedia	ppt[11)], HTML	✓	✓	Metadata, publishing assistant
TeleTeaching Tool	—	✓[12)]	—	—	—[13)]	any (screen recording)	✓	—	—

1) Semi-automatic conversion; dynamic replay of annotations is lost.
2) A PowerPoint 2000 add-on converts slides, retaining basic PowerPoint features.
3) PostScript import possible in the Linux/UNIX versions.
4) No automated process, some manual work is necessary.
5) A basic AOF editor is available for Linux.
6) Depending on the format and player software.
7) Slides are in HTML. Audio and video are replayed in a Java applet. To replay other streams, the applications used for recording must be installed on the replaying machine.
8) The applications used must be RTP/I based.
9) Visible scrolling is not possible in RealMedia format.
10) Including animations and embedded objects (video etc.).
11) PowerPoint Slides are converted to GIF or JPEG images, resulting in loss of most PowerPoint features.
12) No built-in annotation facility, but those provided by suitable applications (e.g., Adobe Acrobat, mb) can be used.
13) Audio is in MP3 format.
14) Slides are imported as GIF or JPEG images, HTML pages remain.
15) No dynamic replay of annotations.

Table 1: Overview of presentation recording systems and supported features

BEST COPY AVAILABLE

4. Overview of Existing Systems

Although a variety of presentation recording systems is available today, none of them can be considered ideal in the sense that all of the features listed above are supported to a satisfying degree. (Tab. 1) provides an overview of a number of existing systems and the criteria they meet.

The major conflict between different criteria is easily identified: Screen grabbing systems are very flexible in that they can record almost any material, while all other systems are restricted in this respect. On the other hand, none of the screen recorders are able to automatically create structured overviews of the courses, a feature which is extremely important for comfortable navigation in web-based lectures (Brusilovsky 2000). Moreover, information retrieval in large repositories of recorded presentations becomes difficult or even impossible if the data of the recordings are not stored symbolically.

One way out of this dilemma of conflicting criteria seems to be a presentation system offering an integrated screen grabbing utility that can capture external applications on demand and automatically link the screen recordings with the rest of the presentation. At the moment of writing, we do not know of any such system.

5. Technical Challenges

Apart from the problem of finding a good compromise for the conflicting criteria indicated above, there is a number of technical challenges which need to be addressed, both hardware and software related.

One example of a desirable feature would be a convincing implementation of an optimal user interface for lectures, including, for example, gesture recognition in order to erase, collapse, or expand handwritten annotations. It is obvious that the currently dominating desktop paradigm is not adequate for a lecturer interacting with a wall-sized interactive whiteboard. A number of convenient tools like an "e-sponge" are required in such a scenario.

Lecturers using a pen-based input device during a computer presentation tend to make extensive use of it. Unfortunately none of the currently available presentation and recording systems maintains the individual and personal flavor of the lecturer's handwriting. In fact, the writing often looks scrawly and childlike. The fact that none of the recording tools is able to use all the information provided by modern input devices (e.g., the weight put on the electronic pen) is only one reason for this.

The more serious problem is that the trace of the pen is often just stored as a sequence of input vertices. Processing the handwritings by anti-aliasing or online smoothing may improve the appearance of the pen trace. However, no satisfying compromise has so far been achieved between the conflicting goals: symbolic, vector-based representation of recorded free-hand writing on the one hand in order to keep the amount of data low, and support of pixel-based operations (such as erasing, insertion, deletion), personalization and adaption to different pen styles (chalk, ink, etc.) on the other hand.

6. Conclusion

Presentation recording can be used as a cost and time saving method to create web-based course materials from live lectures. Our experience gained in two government-funded projects (ULI 2002, VIROR 2002) involving several German universities has shown that lecture recording is well-received both by instructors and by learners. Within the past years, more than 250 hours of computer science classes have been recorded with different tools at our university and have served as a basis for web or CD-ROM based courses.

In this paper we have described several technical approaches and presented a list of criteria by which different recording systems can be evaluated for their use in a traditional university environment. One major problem we have identified comparing the tools available today is the conflict between a symbolic representation of contents in recorded documents on the one hand and flexibility regarding the range of recordable formats on the other hand.

There are features which most currently available presentation recording systems leave to be desired, such as a satisfying support of alternative human-computer interaction paradigms, which would allow instructors to completely maintain their familiar style of teaching. Another area of future investigation is a data structure to represent dynamic handwritten annotations on slides in a both comfortable and efficient way, supporting vector-based as well as pixel-based operations.

Professional Skills Training for Social and Behavioral Competence: A Corporate Case Study in using a Fictional Video Script for interactive "learning by viewing"

Sylvie Leleu-Merviel, Nicolas Viéville and Michel Labour
Laboratoire des Sciences de la Communication
Université de Valenciennes et du Hainaut Cambrésis, France
sylvie.merviel@univ-valenciennes.fr

Abstract: Faced with a fast changing society, the need to develop versatile instructional materials to update the professional skills of experienced practitioners has become a major necessity. It is in this context that we will outline the framework of how the project called *Je peux vous aider ? (Can I help you ?)* was developed. It concerns the training of all the sales teams of a major chain store in France. A premium was put on helping professionals in the field to be more aware of their verbal and non-verbal behaviors. To do this, a series of hybrid pedagogic techniques was used, which included traditional lectures, role-plays, a self-study video, a DVD-video and e-learning. This involved making the content matter as attractive and varied as possible so that learners can acquire knowledge easily in their own way. It is in using a type of instructional design like the *Scenistic Approach* that one can ensure the appropriateness of both the pedagogic scenario and its content.

Introduction

Encouraging adults to improve their knowledge in areas in which they feel they are already competent can be a particularly challenging task. This is especially true in the field of professional training[1] with experienced practitioners who are considered to be experts of their domain and so tend to see training sessions as a calling into question of their acquired skills (cf. Theory of cognitive dissonance, Festinger 1957), when in fact both research and technological changes induce a natural evolution of their craft. In this sense, this target population is more demanding, less docile, and less receptive to training sessions than, for example, their more inexperienced colleagues.

Given this, one of the challenges of lifelong education is to create instructional materials that facilitate an on-going learning process. Consequently, human resources managers invest a lot of money in staff training with often disappointing results in the quality of the final outcome. This is generally due to an inadequate evaluation of specifications. And while Information Technology (IT) can often play an important role as a solution to this type of training, but not in every case, work in the domain (*e.g.* Leleu-Merviel 1996) shows that "scripting a lesson" is an important strategy in improving the effectiveness of the teaching/learning process.

In this context, we first describe, in Section 2, the framework for analyzing the training needs and its practical implications. This is followed, in Section 3, by an explanation of the chosen aims of the instructional requirements. This involves a discussion of the pedagogic implications of having chosen different approaches to meet the designated requirements. The fourth section details how the five-step *Scenistic Approach* has been used with its *diagesis, narrative canvas, scenation, scenic* and *setting up the situation*, phases in terms of the overall structure of the *Je peux vous aider ?* (*Can I help you?*) training DVD-video, and its role vis-à-vis other teaching tools, like those of IT. Finally, in Section 5, we consider the different "patterns" of practical implementations, and their technical limits, aimed at improving their real effectiveness in satisfying client expectations concerning the required characteristics of the educational product.

---

[1] Definition: "Training" in this context implies a "planned process to modify attitude, knowledge, or skill behaviour through learning experience to achieve effective performance in an activity or range of activities. Its purpose, in the work situation, is to develop the abilities of the individual and to satisfy the current and future needs of the organisation" (Manpower Services Commission, UK, 1981) Lesson 11, *B.A (Hons.) Business Studies*. Bolton Institute, UK cf. http://www.bolton.ac.uk/campus/business/babus/humanresource/restricted/hrm_lesson11/hrm_lesson11.html (Retrieved 9.12.2001. The Welsh concept of *hyfforddi* (to train) offers the complementary notion of "making the way flexible" for the learner, as opposed to *addysgu* (to educate, to instruct) based on the Latin notion of *scala*, (ladder, "a climbing device").

Analysis of corporate needs

In needing to make access to the content matter attractive and varied, one invariably has to comply to a quality-based approach, given that:

Definition : Quality designates the capacity of an entity to satisfy the needs and wants of users (Merviel 1977).

In this particular context, the analysis of the instructional needs can be summarized by three basic questions:

(1) Who are the immediate stakeholders[2]?
(2) What are their expressed needs and wants?
(3) What are the desired outcomes?

The answers to these questions provide a basis for establishing the parameters of the instructional context and the ensuing "pedagogic scenario".

Who were the immediate stakeholders? The principal direct stakeholder was a regional Human Resources Director in charge of training all the sales teams of one of France's major chain stores in the region of *Nord/Pas de Calais*. At the time, he was in a process of giving each and every sales assistant face-to-face training, which was to be followed up by regular refresher courses with the aid of technological supports in order to maintain employees' newly acquired skills. As this was an expensive scheme, he wanted to get value for money from the investment long after the official face-to-face training sessions had been completed. Other major stakeholders were: the managers of each of the different chain stores, of this northern region of France on the border of Belgium; the company's employees, namely the sales assistants as the end-users of the instructional material.

What were the stakeholders' expressed needs and wants? The issue to be addressed was the upgrading of sales assistants' professional skills by regular and varied in-house training sessions after having received face-to-face courses. There was also the challenge of making the training content available to (new) sales assistants that had not attended the face-to-face training sessions. This meant that new instructional material had to be versatile so that it could be used both in a traditional, guided instructional situation, as well as for personal self-study. Furthermore, the technology to be used had to be that which already existed in the work place *i.e.* VHS videotapes, paper-based documents and email. Interactive multimedia resources, like the DVD-ROM, were excluded because it meant buying new equipment (e.g. multimedia computers) that would have exceeded the training budget.

What were the desired outcomes? The essential objective was to show sales assistants how to adapt their verbal and non-verbal behavior to the needs of customers. This was to be done by helping the employees to better understand company policy, in dealing with customers, for whom the ideal sales assistant is someone who is: well groomed, welcoming, polite, open, reactive, available, smiling, courteous, respectful, in a good mood, punctual, responsible, organised, competent, a good listener, silent, curious, dynamic, convincing, honest, lucid, patient, reassuring, motivated and autonomous. In this context, the instructional material had to help learners become more efficient in their sales techniques by focusing on practical problems encountered at the stores.

The instructional objectives

Given that the main pedagogic objective was to modify behavior patterns (procedural knowledge), this meant a more theoretical (declarative knowledge) approach to customer service was to be limited. It therefore seemed appropriate to adopt a pedagogic approach that built on the existing knowledge of sales assistants in such a manner that they could be led to construct, in their own way, what professional behavior needed to be avoided and which were to be encouraged. In this context, it was decided to use an approach of demonstrating key concepts through examples. This implied carefully staging a fictional series of typical professional situations to which learners could easily relate to based on a variety of e-learning and more traditional learning supports.

Our approach is underpinned by the ground breaking work of Treicher (1967) who reminds us in his book, *Are you Missing the Boat in Training Aids? Audio-Visual Communications*, that most people "learn" (retain) 10% of what they read, 20% of what they hear, 30% of what they see, 50% of what they both see and hear, 70% of what they discuss with people whose opinions they value, 80% of what they personally experience, and 90% of what they teach other people. A training program should therefore go beyond providing teaching aids that learners can both "see and hear". The pedagogic scenario of instructional materials needs also to focus on the human interactional elements of learning to include meaningful "discussions" and "teaching" other people (e.g. peer learning), so to transform input into personal learning experiences. In this light, an interactive learning solution based on a video/film format offers some specific advantages, as highlights the film historian Turner.

---

[2] Definition: A *stakeholder* represents groups of people or individuals that can have an influence, in this case, on the training needs. Researchers R. Oudman, A.M. Vos, and J. Biesboer review various methods of "Stakeholder Analysis" at http://panoramix.univ-paris1.fr/CRINFO/dmrg/MEE98/misop001/ (retrieved 27.10.2001).

> ... (with) the abandonment of the idea that there was a core of meaning in a film which the audience had to discover. Meanings are seen as the products of an audience's reading rather than as an essential property of the film text itself. Audiences make films mean: they don't merely recognize the meanings already secreted in them (Turner 1988:121).

A training scenario should then, for example, get learners to discuss how they saw a scene and how this relates to their personal experience and its future implications for them. It is in such domains that network-based technology like the Internet (with its discussion forums, chats, emails, etc.) can facilitate learning by communicating with different people. That said IT, like Internet, is not in itself pedagogic. What makes these tools so, is the appropriateness both of what is put in them (content) and how this is done (method), hence the need for operational frameworks such as the *Scenistic Approach*, and other related ones, aimed at making optimal use of the content.

Using the *Scenistic Approach* to draw up the pedagogic script

Our human resources director was particularly concerned in capitalizing on his investment. So his first request was to ask the audio-visual specialist at the University of Valenciennes to simply film series of traditional talk and chalk, face-to-face training courses.

It would not have been strategic to reject out of hand this first request of the paying client. So we did what we were asked to do. We gave to the company 40 hours of video tapes... that, as it turned out, have never been used, as we had anticipated right from the start. From a pedagogic point of view, the tapes were not, educationally speaking, quality material, because they do not match the needs and wants of the users, *i.e.* the sales assistants (and not those of the human resources director). After this first failure, it was not very difficult to convince our client to try something else, namely a specially written video fiction as pedagogic input to facilitate learner self-critical reflection. This was done based on the principle of the *Scenistic Approach* (Leleu-Merviel 1996) in providing a framework for scripting a series of "events" in a way that it ensures overall coherence and transparency in the design process. The technique has five major steps: (1) diagesis, (2) narrative canvas (3) scenation, (4) scenic, and (5) setting up of the situation.

Why, then, is this type of solution better suited to the needs and wants of users?

Diagesis. The diagesis involves everything that belongs to the imagined/proposed setting of the document as expressed through the (lesson) content. In this case, the universe of the film is exactly the same as the reality of the sales assistants. The story physically takes place in a real store. The employees can therefore identify themselves with the situation. Even if it is simulated by actors, it is a real situation of daily professional life of learners.

The diagesis also includes taking stock of, for example, the different educational paradigms and approaches that could be used to achieve the objectives identified in the analysis of the instructional context. In this case, it was decided that learners would be systematically encouraged to first identify professionaly inappropriate behavior or elements in the scenes presented to them, followed by suggesting a possible solution to remedy the situation. It was hoped that by using such a "constructivist" inspired approach (cf. Jonassen *et al.* 1999) new knowledge would graft itself onto existing knowledge structures.

Narrative canvas. The second step of the scenistic approach is selecting appropriate events that will constitute the narrative canvas. At first sight, the events included in the film seem crudely exagerated. And seeing it for the first time, the sales assistants laugh at the behaviour of their video-clones, because they come across as being so unprofessional. In fact, the corporation has a customer relations quality-reference book where an exhaustive list of *Quality Points* (QP) is given for each type of behavior for sales assistant when dealing with a customer. To be a "perfect" sales assistant, it would be theoritically sufficient to know all the QP by heart and to comply to them. To ensure the company's policy is applied, some "mystery-clients", that is undercover quality-inspectors, regularly go to the store to write up reports about the quality of its customer-relations by enacting a purchase-need situation with a sales assistant, unbeknown to that person. Based on some of these reports, every situation integrated into the narrative canvas of *Je peux vous aider ? (Can I help you ?)* was in fact experienced by a mystery-client.

For instance, when the transaction is not immediatly concluded, the sales assistant has to promote the client's fidelity to the company in writing down the item's references and the client-advisor's name on a special company client "Contact Card". So, for example, what can be seen in Scene 15 of the film, *Je peux vous aider ? (Can I help you ?)*, is not a figment of an author's fertile imagination. Scene 15 depicts a real situation where a sales assistant, called Michel, did in fact write down an item's references and his name, not on the Contact Card, but on the nearest bit of paper on hand, in this case the corner of a page from a stock taking list. The information noted down was then rapidly torn off and given to the "customer". The piece of paper was duly put into the quality-controler's report ,of which a copy can be seen in Figure 1 below.

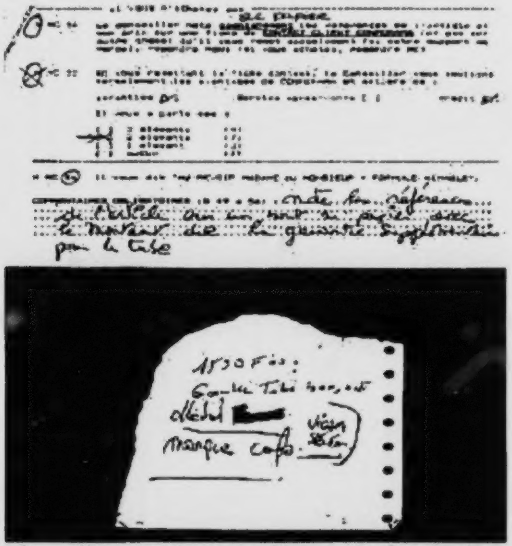

Figure 1: A partial copy of a quality control report, with a scrap of paper given by a sales assistant to a "customer" indicating the name of the client advisor (Michel) and details of an item on sale

The same process was used for other inappropriate behaviour that were then included in the film. In short, everything portrayed in the film happened at least once to the undercover quality control inspectors.

Scenic: The scenic transposes the narrative canvas into concrete, hands on reality. It is at this stage that one makes aesthetic and logistic choices within the limits of the practical and financial constraints, conditions of usage, etc. This includes the choice of appropriate props for the written scenes.

In this case, the shooting of the film was done in a real store of the company. The employees can recognize the familiarity of the surrondings, and can therefore identify themselves with the situation. After shooting and editing, the film is finished, it can now finally be used.

Viewing is not learning : different patterns of pedagogic use

Little can be really learnt by simply viewing the film, because viewing is not learning. This may seem self-evident, but it is all too often forgotten. Pedagogically speaking, it is essential to define a procedure in how to use the material to ensure, in this case, that sales assitants hone their skills to: make clients feel they are the centre of attention; take stock of the clients hopes and dreams; propose the appropriate products; master particular sales techniques; and activily participate in a dialogue with the client.

The first anticipated use of the video was that of a guided learning game. The head of each sales assistant coaches his/her team, and focuses on a theme for each training session. After observing the scene on the VHS-video as many times as necessary, learners are asked to identify recommended behavior ("Positive points") from dysfunctional behaviors ("Negative Points", "Problems related to manners or behavior"). Finally, some "points of reflection and development" are suggested for further discussion. In this way sales assistants have to discover all the good and bad points of a chosen scene. The coach has the teacher's booklet, which identifies the positive points, negative points,

BEST COPY AVAILABLE

problems concerning manners or behavior, and open questions to raise further issues and develop critical self-reflection. For example, the coach's check-list concerning the first scene (Theme: Answering the telephone) can be seen in Figure 2. Of course, learners (players) must never see the check-list. They only know the number of points they need to discover to win. Some QP are easy, but others are very difficult to find *e.g.* a prohibited-open jacket with the company shirt.

Scene 1: Prologue and answering the telephone
Length: 1 minute 30
Start mark: 1mn20. Stop mark 2mn53
Staff concerned: all

☺ **Positive points**

QP1	The person picks up the telephone before the 4th ring (less than 4 rings).
QP3	The person is not chewing gum.
QP6	The waiting time is less than 30 seconds.

⊗ **Negative points**

QP2	The person does not mention the company's name.
QP2	The person does not mention the name of the store where s/he works.
QP2,7	The person does not say "Good morning".
QP2,7	The person does not present him/herself with his/her first name.
QP7	The person does not indicate in which department s/he works.
QP3	The person replies in a muffled voice without articulating.
QP4	The person does not reply to the client's question.
QP4	The person does not connect the person to the correct department.
QP8	The person replies in a disagreeable way, making it clear to the client that s/he is tedious.
QP5,9	The person does not say "Goodbye Madam" at the end of conversation.
QP5,9	The person does not add a friendly word, nor a polite one at the end of the conversation.

✍ **Problems related to manners or behavior**

- The person interrupts the client while s/he is speaking.
- The person asks the client to call back later.
- The person hangs up on the client.

☞ **To go further, points of reflection and development**

(1) The person justifies him/herself by mentioning the problems in the store: "I am alone". How could the person have avoided this situation?
(2) The person gives a negative image: "I don't know". What should the person have said?
(3) One should never ask a client to call back. What should one do?

Figure 2: The coach's check-list of the first scene

In reality, the training material has never been used in this way. This is mainly due to the fact that the "linear reading" paths of the videotape is not appropriate for such educational use. For example, one cannot easily find the exact spot of a scene on a video recorder in order to play the "game" well. The issue of "reading paths" is a matter of the "scenation" (for example a traditional film has a linear scenation) *i.e.* the third phase of the *Scenistic Approach*. The solution to this technical limit of the traditional linear film is to change the scenation, and to convert the linear format into a more flexible support. In this case, the DVD, which allows the film to be to be split up into fragments so that users can access different part of the film directly, and read them in any sequence they wish, and as much as they need to. The DVD-Video was chosen, because the workstation is a standard television-set, a DVD-player and its interface is an ordinary remote-control. Though the DVD-video does not have the flexibility of a key-board, mouse, or computer, its format offers a high quality of images and sounds.

"Setting up the situation", or the fifth and final phase of *Scenistic Approach*, defines the practical ways that the user can in fact access the (video) fragments of the document *via* user-functions. Taking into account the potentially laborious linear and sequential navigation of a remote control box, as compared to a free flow approach of a computer "mouse", special icons were created to help learners go through the DVD-video document efficiently. In this way, the relatively few interactive possibilities of the DVD-video format could be put to profitable use. Given that, the ergonomics of the interface must suggest navigational functions *via* identifying symbols, the colors of the company were chosen as the guiding color scheme to present the interactive pages of the DVD-video. Blue, pink, yellow, green and orange hues were added to identify the five different themes in order to facilitate user-navigation and to make the document more attractive. In this context, 17 icons were designed to be meaningful to the user.

In order to get maximum use of the specially written scenes, a 25-page booklet was also printed for learners to help them use the material. A separate booklet was done for trainers. These booklets were linked to more general guidelines concerning the different skill-based learning tasks that could be done on-line and off-line with the DVD-video. This included ways of making learning less tedious and more motivating, *via* active learning tasks such as role plays, competitive and collaborative activities, for example to win a prize for getting the maximun QP in a minimum of time in using the electronic network and face-to-face situations. In short, the DVD-video is only one aspect of a pluri-media learning package that includes e-learning.

Short of using more elaborate networks like the "Video On Demand" system, the still evolving state of the Internet limits the present use of high quality audio-visual materials, which demand a certain level of fluidity and picture quality. This latter point is particularly important when inciting learners to observe non-verbal behavior and language, *e.g.* a badly knotted tie, where the quality of the images could be a determining factor.

Conclusion

Clearly e-learning is here to stay for better or for worse. From a technical point of view Civanlar (2001 p.433) is optimistic about video delivery on the Internet. He banks on the greater availability of higher access bandwidth, server load and network traffic reduction, and an increase in backbone bandwidth. Indeed, technology like the Synchronized Multimedia Integration Language (SMIL) facilitates video delivery by reducing multimedia content to speed up the time it travels on the Internet. Based on eXtensible Markup Language, SMIL separates multimedia content into different files and streams (audio, video, text, and images), transmits them to individual computers, and then have them displayed together as if they were one multimedia stream (cf. McCannel, 2000, *Multimedia for the Masses*). It is in this direction that our research is being taken to make audio-visual documents a greater part of e-learning, beyond the current, largely written text-based, approach to e-learning. That said, decades of experience in distance learning has unequivocally shown that "the lack of personal contact between the learner and the student is the biggest weakness" of this type of education and training (Noffsinger 1926). In effect, the challenge of e-learning is not only to transmit content, but also to ensure that learners appropriate it from a cognitive point of view, for "viewing is not learning". In short, it is only when the technical possibilities of electronic networks match that of the pedagogic demands of e-learning, that we can truly envisage the possibility of a Global Village that is not only technically efficient but also of high educational quality.

A Drag and Drop Editor for Interaction and Personalization of Web Pages

J. Lennon
R. Warburton
Department of Computer Science
University of Auckland, New Zealand
j.lennon@auckland.ac.nz

Abstract: In this paper we examine two key issues in Web learning interaction and personalization. We discuss how a simple drag-and-drop application enables users to create and modify Web pages in ways that (1) increase interactive learning experiences and (2) make the best use of their individual differences.

Introduction

The importance of interaction in learning environments is exemplified by the range of research covered by journals such as the Journal of Interactive Learning Research (JILR)[1]. This has led researchers to question how Web learning can be made more interactive (Harasim, 1990, 1997) and hence better support individual differences (Belanger & Jordan 2000; Jonassen, 1997). Many solutions have revolved around networking. However, apart from the inclusion of web links and inline tests, it has been comparatively difficult to make Web pages more interactive. The existing backlog of valuable resources on the Web in the static formats makes the problem significantly worse.

Initially our work focused on addressing issues such as these from an authoring perspective. We aimed at developing a Web application that was so simple that teachers could much more easily incorporate different types of media into their Web pages. However, because the application is so easy to use, students themselves are interacting with pages in ways that reflect their own individual differences.

Catering for Differing Modalities in a Web-based Environment

The number of Flexible Learning centers around the world is increasing and many are well equipped with instructional designers. The dilemma is that there are simply not enough such centers to go around and teachers and academics are pressured to take minimalist approaches to putting "something" on the Web. What we are seeing is a proliferation of PDF and PowerPoint documents. Not only are these hard to cross-index and search, they also offer very little interaction.

At this point we must indicate what we mean by "interaction". Certainly not the flashy gizmos seen all too frequently. Although email, forums, video links, interactive quizzes, etc., all have a place, the challenge is converting existing Website pages, which have static text and maybe a few pictures (probably just for decoration), into pages where students have real choices. Research suggests that students can gain by having alternative representations of media (Hobbs & Christianson, 1997; Reyna et al., 2001). In addition, research indicates that some students prefer visual representations, while others prefer more verbal modalities (Jonassen & Grabowski, 1993; Reyna et al., 2001). In the *Handbook of Individual Differences, Learning, & Instruction* (Jonassen & Grabowski, 1993) the authors give guidelines for supporting students with visual/verbal preferences. They not only list options to capitalize on strengths, but they also ways suggest ways to compensate for deficiencies.

The implications of different learning styles are also complex. Much research follows Gardner's *Theory of Multiple Intelligences* (Gardner, 1985) and Pavio's *Dual Coding System* (Paivio, 1971; Paivio, 1986; Anderson, 2001). More recently, cognitive scientists have thrown considerable light on how our visual memories work (Kosslyn, 1994; Pinker, 1999). However, there are conflicting views on how this applies to learning (Denzine, 2001). Anderson (2001) concludes that "... much depends on the exact nature of the material being presented and the type of media employed".

---

[1] http://www.aace.org/pubs/jilr/default.htm

Notwithstanding the "imagery debate" (Kosslyn, 1994) that still rages (although in a transformed form) (Pylyshyn, 2001), our classroom experience finds that while some students "like" pictures others find them a distraction. Some like sound, others do not. "Some respond to aural cues while others are visual learners" (Smith & Ransbottom, 2000). We believe that there will be interesting research results appearing when tools like the one we introduce in the next section are readily available.

	Capitalize	**Compensate**
Visual Preference	· [2]using images, pictures, graphs o charts · using high-imagery materials · using graphic organizers * using video games	* using multisensory training * using concrete to abstract sequencing * presenting word images * presenting special text in window and boxes * underlining, visual cueing in text
Verbal Preference	· using verbal presentations * using textual outlines * using abstract to concrete sequencing	* using multisensory training * using graphic cues, lines, boxes with text, arrows highlighting images

Table 1: Visual/Verbalizer and Instruction [Redrawn from Jonassen & Grabowski, 1993]

A Simple Drag-and-Drop Web-Page Editor

We have developed a prototype Drag-and-Drop Editor (DDE) that has the following key features:

- Works from within a web browser (Mac IE5 and Mozilla) enabling users to edit pages directly, without having to download any special software or concern themselves with uploading their pages to the server.
- Has drag and drop methods for placing objects on the page. This makes it extremely easy to use. Placement to pixel accuracy. Pictures and text blocks can be placed and dragged to exactly where users want them.
- Automatic recognition of multiple media types (audio, video, text).
- Automatic handling of media storage.

---

[2] The authors use bullet points to indicate that inferences are drawn from research, while stars indicate that they are "drawn logically from descriptive information".

- Easy resize functionality. (Resizable objects have resize tabs.)

Textual alignment (left, right, center and justify).

- Control of Background color
- Color Borders
- Object duplication

Transparency control. (Users have control whether certain layers are transparent.

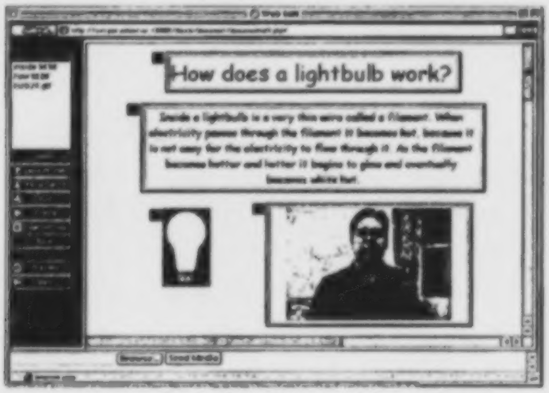

Figure 1: The WebEdit Environment

User Testing

User testing was undertaken at Papatoetoe Central School, Auckland, New Zealand, in three stages. Stage One was an introduction to the system asking teachers how they found WebEdit and whether they had any suggestions to improve it. Stage Two was a follow up session two weeks later with most of their suggestions implemented. Stage Three was testing with a small group of children.

Tests with Teachers

Prior to using WebEdit staff had to use four separate software applications to maintain their class Web pages: Adobe Pagemill for editing web pages, Graphic Converter for image file conversion and resizing, Appleshare for transferring files and Netscape to check how their page looked. As staff had only rudimentary training in these applications, they reported many problems. In addition, some staff asked questions such as, "why can't we place an image 'anywhere' on our pages?" Our aim was to produce an editor that was as simple to use as any word processor.

All 26 teaching staff volunteered to test the WebEdit system in the school's computer suite (17 iMacs running IE5). The session started with an introductory seminar explaining how the system worked, then they were given a short user-testing sheet and encouraged to trial the system. Staff were told in advance that the web pages created in WebEdit were for testing purposes only, there were no expectations on them and it would not interfere with their currently maintained pages. A few staff opted to work in pairs. All staff were successful using WebEdit to make a web page including those who considered themselves "I.T.-unfriendly".

Surveys

Most of the survey questions concerned implementation improvements that have now been implemented. However there were three general questions that we include here:

BEST COPY AVAILABLE

Question One: "Would you prefer using WebEdit over the current system?" All 26 staff members answered positively. However to try and avoid bias the staff were asked to justify their answer. Most said it was "faster" and "easier to use". We believe that this is probably because only one program is used rather than four, which eliminates time spent switching between applications, and minimizes the mental demands of having to deal with multiple applications' operational models. One teacher wrote: "Child friendly, quick and can use in front of class."

Question Two: "Was there anything that you particularly disliked about the system?" All but one answered no. In the latter case the teacher stated that found she found the information button hard to see. It is interesting to note that this button was the only one to use primary blue. The color of the button has now been changed to yellow.

Question Three: "What features would you like added?" Three teachers asked that the alert box, that appeared each time media was loaded, be removed. This is perhaps because the staff did not need to know, how the media was going to be handled.

Tests with Students

We asked 10 children, aged 611, to create a web page that presents, and answers, a single question about light ("How does a light bulb work?"). Their aim was to create a web page that one of their friends could learn from, as quickly and easily as possible. They were presented with a question and an answer in multiple media forms: text, audio and video. The audio was someone reading the text. The video was someone looking at the camera saying the text. As such, each media type provided no more information than any other. The children were allowed to decide which media was most appropriate for the needs of their friend. Multiple media selections were permitted. Additional images were included only to help the aesthetic presentation of the page, but offered no information.

Unfortunately, due to end of semester time constraints, we were not able to survey the children after they had finished their pages. All children created their pages in the allotted time (20minutes). However, what we thought was most interesting was the prominence of the video on the page that 9 out of the 10 children used.

Table 2 indicates that younger children tend to avoid text in preference to audio and video, whilst older children tend to use text, only using other types of media to enhance the page.

Nevertheless, we realize that unknowns such as novelty factors may have biased these findings.

		Question			Answer			Used Video
Student	Age	Text	Audio	Video	Text	Audio	Video	
				X		X		X
			X				X	X
			X	X	X			X
				X	X			X
		X			X		X	X
		X		X	X			X
		X		X	X			X
		X			X		X	X
		X	X	X	X			X
		X			X	X		

Table 2 Student Testing Results

Two Examples of Children's Pages

Figure 2 shows two screen shots of web pages designed by children aged 6 and 11. All objects are moveable and scalable. The sound and video icons are playable.

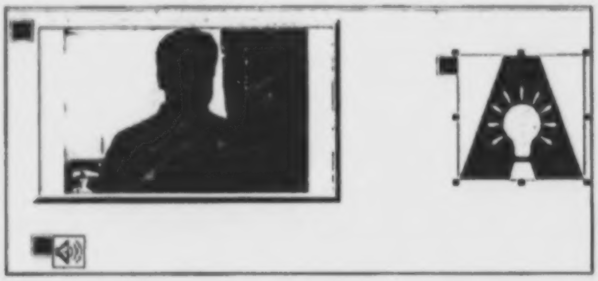

Figure 2a: Page by a six year old.

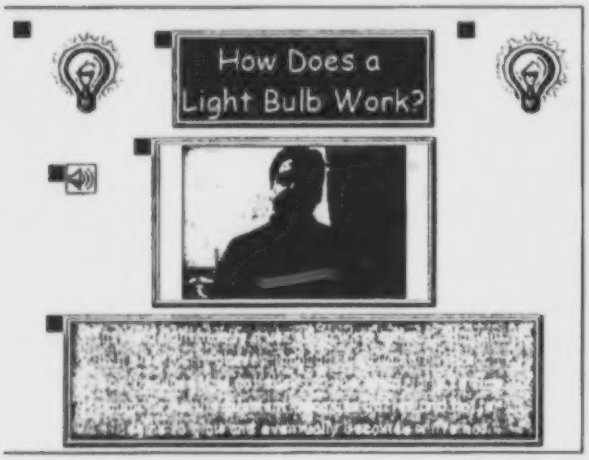

Figure 2b Page by an eleven year old.

Conclusion

Our initial aim was to provide authors with a simple drag-and-drop tool so that busy teachers could more readily add alternative representations such as text, images, sound, and video to their Web pages. It is noteworthy that some teachers moving to different schools next semester want to take WebEdit with them. However, perhaps of greater interest, is that since the editor is so simple to use we now see children interacting with the pages to a much greater extent than they did before. They can change the relative importance, as they see it, of the various media objects by increasing the size of some objects while demoting (or deleting) representation that they do not need.

HWONS: A Hyperwave Online Negotiation System

J. Lennon, H. Liu
Department of Computer Science, University of Auckland, NZ
Email: j.lennon@auckland.ac.nz; lhdh_h@hotmail.com

H. Maurer
Technical University and KNOW Center, Graz, Austria
Email: hmaurer@iicm.tu-graz.ac.at

Abstract: We have developed a Web-based negotiation system that is closely modeled on real-world transactions. In this paper we illustrate the generality of the system by discussing two disparate applications of the system: one taken from business and the other from collaborative e-learning. In the business context we look at online employment negotiation. In the e-learning case, we discuss a scenario where a large (or small) class of students interacts with team leaders to form groups for project work.

1 Introduction

Since our application is built on top of the Hyperwave (HW, 2001; HWTW, 1999; Maurer, 1996) knowledge management system (Borghoff & Pareschi, 1997), it inherits the adaptability of a commercially robust hypermedia system, with advanced access rights and document attributes. This paper shows how, building on these features, an online negotiation system can be designed to be interactive, personalized and scalable, while supporting user-controlled degrees of privacy. Interestingly, the negotiations can be supported in ways that more closely resemble traditional methods. These processes aim to find the "right person for the right job/team" – and it is usually an iterative process.

The application generates, in real time, transparency-controlled networks of virtual connections between users. We shall first look at the general features of such a system before applying them to employment negotiations. We shall then describe how the same system can be used in an e-learning environment for matching team leaders/mentors/tutors with groups of students.

The effectiveness of our system is based on three factors:

A good knowledge management system (see Section Two).

User-determined levels of privacy (see Section Three).

Iterative, computer-supported interactions between users (see Section Four).

2. The Hyperwave Knowledge Management System

Hyperwave[1] was developed to store high-volume hypermedia resources, which can be spread over multiple servers (HW, 2001; HWTW, 1999). Hyperwave has a more sophisticated design model than most Web server systems (Maurer, 1996). For example it supports the following attributes:

---

[1] http://www.hyperwave.com/index.html

- Read and write permissions for groups and individuals
- Extra search keywords
- Titles in different languages
- Display properties
- Custom attributes
- Setting of a time period during which the document is visible to the public.
- Version control
- Similarity recognition of documents

Since attributes are not stored within the objects (as in most Web servers) but in a separate database, they can be efficiently extracted and manipulated. In addition, objects can be locked to ensure they are not updated concurrently. It is features such as these that are utilized in our negotiation system.

2.1 The Hyperwave Online Negotiation Environment.

The three main parts that form the environment for our Online Negotiation System (ONS) are illustrated in Figure 1, reading from left to right.

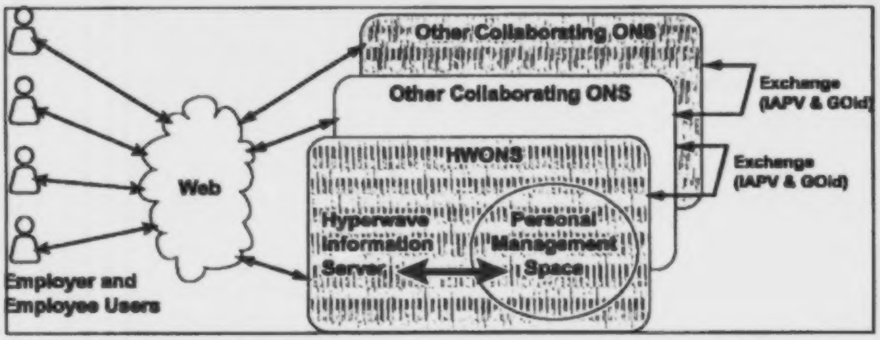

Figure 1: An Overview of the Hyperwave Online Negotiation System

The negotiation system receives information via Forms and stores and updates the information in a Personnel Management Space. This is a Hyperwave database that contains personalized records and automatically generated attributes (HWTW, 1999). After storing the necessary data about the negotiation parties it will search through the Personnel Management Space, matching attributes, and return the results. Users can then update or delete any of the details they have already sent to the system and request new services such as further negotiation.

2.2 The Expression of User's Details in a Compact Vector Format

Key attributes for any pair of negotiators are identical but complementary in meaning (what an employer requires is what an employee should posses, and vice versa). To keep things concise, yet meaningful, we choose strings (*UAPVs*) that combine characters for attribute names, and digits as the corresponding values (actually, index-numbers in predefined lists). Using this format, the sequence of attributes in a *UAPV* can be arbitrarily ordered, and the length can be flexible. Hence we can use the same *UAPV* format for the two types of users, and the searching process involves matching vector couples.

BEST COPY AVAILABLE

Since different users will have different priorities (e.g., some people may regard job location is the most important factor, but others may consider salary is more important) we also use a weighting process to assist *UAPV* matching. The *UAPVs*, together with the importance sequence (weighting), and other system-required information, are then stored in the Hyperwave document management system.

3 Transparency-Controllable Virtual Connections

In many negotiation situations privacy can be a key issue. People may have confidence in a human agent but do they trust an online system with just a few lines of privacy policy statement? For example, a statement of privacy may not be good enough if users can just post their background information without any options to "hide" and control them (CntPub, 2000). Neither does it make users feel "safe" enough, if a sufficiently interactive mechanism is not provided. Furthermore, the system should allow users to request services like 'Please let me know what you have found for me before you show my real name (or other details) to the other negotiator ...'. Thus it should be the users themselves who are permitted to set which, and when, private details are visible to the other party in the negotiation. Hence, the virtual connections should be *transparency-controllable*.

Thus, users can keep many details hidden, particularly in the first stages of negotiation. It is important to note that searching and matching can be performed on all stored data and not restricted to the visible attributes – even though users may be unable to see this information.

4 Negotiation Cycles

As mentioned previously, the matching of employers and jobseekers, or moderators and group members, is usually achieved by negotiation. This means that no matter how good the matching algorithms used are, the system must support iterative cycles. For example, a team leader may have set the qualification level too high, with the expectation that they will be lowered if there is a candidate that fulfills other attributes. Similarly, a student may not be experienced enough to even set a reasonable time allocation for a given project. We propose a system that alerts users at login time of any likely new matches. Then, if any of these candidates are of interest, the system can set up virtual connections. Candidates will be alerted and respond if interested. The process is cyclic as shown in Figure 2.

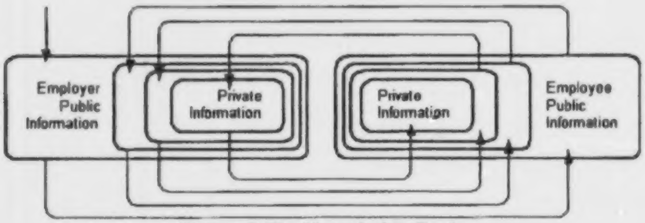

Figure 2 The Negotiation Cycle

Since all matching is done in real time we will avoid out-of-date messages such as those given by CGI scripts and email.

In the iterative negotiation cycle described above, we would expect to see transparency increase. This is because, for example, employer/group leader can invoke the interactive functions of the system to request the employee/student to reveal details appropriate to the stage of negotiation. And, of course, the converse is also true.

BEST COPY AVAILABLE

5. Applications

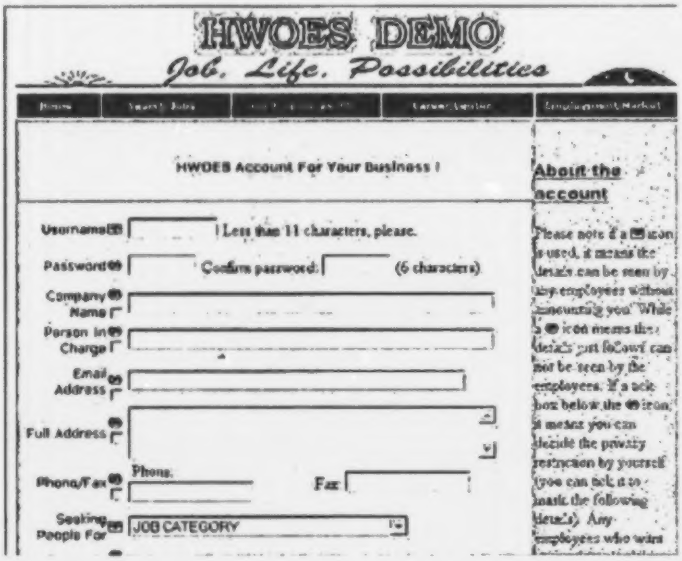
We shall first describe the prototype we have built as an online employment service. This will be followed in Section 5.2 by a discussion of how it can be adapted to an e-learning environment.

5.1 The Hyperwave Online Employment System (HWOES)

The system we have implemented is based on Hyperwave (HW 2001; HWTW 1999; Maurer, 1996) and is called the Hyperwave Online Employment System (HWOES). The implementation details are described in (Liu, 2001; Lennon, 2002). Certainly, online employment systems such as Monster (Mnstr, 2001), HotJobs (HotJ, 2001), Career Mosaic (HeadH, 2001) and The Jobs Company (Jobs, 2001) (to name but a few) handle millions of employment cases annually and are expanding their services steadily. However we have demonstrated that our system has significant advantages, particularly as far as privacy and cyclic negotiations are concerned.

Sign-in Forms for employers (see Figure 3) and employees provide the necessary information items for HWOES. Key attributes that are used to do the matching are clearly pre-defined in option lists to avoid errors. Text, graphics and even videos (e.g. an inaugural television spot for the client) are also supported as attachment documents. Part of the Form for employers is shown in Figure 3.

In the Form, the eye icon ▣ indicates that a prospective employee can see an item, whereas a negated eye ● indicates that, at present, the data is restricted. In the screen shot the icons indicate the default settings for the data. Of course, these settings can be changed by the owners later in the negotiation process. The completed form will then be sent to the Personnel Management Space (*PMS*, the database) to be stored and UAPVs created or updated. Naturally, there is a corresponding Form for employees.



Less than 11 characters, please.

5.2 E-Learning Negotiation

By changing the fields on the two basic data entry and update Forms we can readily transform the application into an e-learning negotiation tool. Let us consider the example of a class that has to form groups for project work in multimedia. Instead of using Forms with fields such as Job, Location, Salary etc., we will have Forms with 'Project name', 'Experience', 'Time to Complete' etc. Now we will have the project leaders negotiate with class members to form the best team for their particular project. For example, under 'Experience' the system may list Instructional designer, Graphic artist, Systems Analyst, Programmer etc. The leader can select and prioritize these requirements. The system will then find the students with the best matching attributes.

Of course there will be competition and here we can see that we have a very good "role-playing" scenario where all the players have to carefully consider how they prioritize their options. For example students will have to carefully consider what they have to offer when they select various projects and, most importantly, just how much time they are prepared to commit to the project. The project leaders on the other hand will be competing for students and they will have to similarly choose the attribute values that they are looking for with care.

6 Conclusion

The proposed system and prototype gives users significant control over the levels of privacy they need during online negotiations. Virtual connections supporting cyclic negotiation between negotiators are set up in real time and can be modified in real time. We have prototyped an online Employment service and now we propose minimal changes to adapt it to other types of negotiations such as those that occur in group learning.

McGill University
Canada
kit.leung@mail.mcgill.ca

Abstract: Diagnostic Cognitive Assessment (DCA) is an alternative dynamic assessment. It aims at measuring cognitive processes for effective learning support & coaching. DCA is embedded in a digital coaching system (DCS) as an executive director. It contains three sub-models: Expert Knowledge Model, Inference Models, & Student Model. While Expert Knowledge Model emulates human tutoring by modeling expert tutor's knowledge, probabilistic inferences of knowledge acquisitions are derived from Inference Models that are driven by Psychometrics and Bayesian Networks. By observing the students' performances, the Inference Models examine & interpret how learners learn as they trace, track, and record learning activities. Student Model delivers customized diagnostic analysis to learners, guidance to DCS's Scaffolding function to map learner's knowledge structure and schema, immediate dynamic diagnosis to Real Time Evaluation of DCS, and aids to collaborative learning in the E-Learning Community.

Introduction

E-learning is expected to provide environments that promote metacognition: thinking about thinking via electronic conferencing, and collaborative learning in the virtual learning communities. It can entail the transformation of learning: from a product to a process. While knowledge is being constructed by individual learners, and co-constructed and shared with peers and experts globally via the Information Communication Technology, it is represented and re-engineered through innovations and creativity with high end technology such as simulations, and electronic coaching system. This continuum involves cognitive processes, learning, and knowledge and skill development. This phenomenon coincides with the contemporary theories of cognition and social constructivism that "emphasize the way knowledge, organized, and processed in the mind" (Pellegrino et. al., 2001, p.3) in a social context in which knowledge is actively manipulated for problem solving.

However, the rise of e-learning also intensifies what Frederiksen (2002) has described as the incompatibility between the conventional measurement models that underlie current practice in educational assessment and modern theories of the cognitive and social processes that are involved in learning and skilled performance, particularly in the dynamic holistic e-learning context. Why? Shepard (2000) stated that the current practice assesses learning achievements as products. It focuses on a) component skills rather than proficiency in solving practical problem in authentic settings, and b) discrete bits of knowledge rather than critical thinking and knowledge application. The assessment goal mostly focuses on giving grades or to satisfy accountability demands. Does this type of assessment support and enhance learning? Shepard (2000) advocated that assessment is for learning, and pointed out that in-depth and ongoing assessment genuinely increases learning. Frederiken and Donin (1999) declared that there has been a growing recognition of the needs for an alternative assessment - more authentic cognitive assessment. This is an assessment that measures performance and achievement, and assists learning and instruction.

Cognitive assessment has been recognized as one of the great challenges for the field of measurement and evaluation (Snow and Lohman, 1989 & 1993; Embretson, 1990; Samejima, 1995; Pellegrino, James W., Chudosky, Naomi, and Glaser, Rober, 2001). I attempt to formulate an assessment framework addressing the assessment of students' cognitive processes and knowledge structures. In this paper, I will describe a cognitive assessment framework that integrates measurement into both learning processes and performances as a vehicle to enhance learning and instruction to the fullest potential. It is named as Diagnostic Cognitive Assessment (DCA). It will be developed and embedded in a digital coaching system (DCS).

Diagnostic Cognitive Assessment (DCA)

Taking the advantage of technological as well as substantive theoretical advances, assessments can improved education. On the one hand, psychometric theory and test design principles are reviewed and expanded, new cognitive assessment theories and models emerge to deal with different measurement issues (Samejima, 1995; Embretson, 1990; Sijtsma, & Verweij 1999; Lesgold et. al. 1989; Junker & Sijtsma; 2001). On the other hand, technological advancement enables rapid and potent measurement potentially. The rise of e-learning as a buzzword for innovative approaches to education implies that I cannot reiterate, or summarize adequately the extensive reports on interesting thesis, promises, cautions, and criticisms that have been published on e-learning. Among all these reports, assessments in e-learning are important but its focus is not on assessing cognitive abilities and cognitive achievements of the students but rather on cost effectiveness. The current assessments in e-learning mostly still remain within the conventional assessment models.

Furthermore, although a learner-center approach, e.g. Veen, Collis, Santema & Genang , (2000), and constructivism, e.g. Hoddinott. (2000), are often the basis for centers investigations, good examples of the integration of diagnostic and cognitive assessments into instruction, learning and testing for e-learning was not found during my literature research. Upon my observation, the current focal point of assessments in e-learning is on how to manipulate technology rather than the assessment itself. .

Technology provides e-learning with a powerful tool for a new possibility. Snow & Lohman (1993 stated that: "The possibility now exists to bring new concepts and measures of aptitude, learning, development, and achievement, together with instructional innovations, to create truly diagnostic and adaptive systems."(p.1). The main challenge is how to use all these available technological advances for the creation of such a diagnostic adaptive system. DCA is to be a response to this remark for a truly diagnostic and adaptive system of assessment.

DCA is generated from cognitive and diagnostic assessments. It focuses on inferences about learning competence. It aims at measuring learners' cognitive processes, learning, knowledge and skill development for diagnostic purposes. Using a medical analogy, a diagnostic assessment is to detect and define an existing learning problem before providing a cure for the problem (Lesgold et. al., 1989).

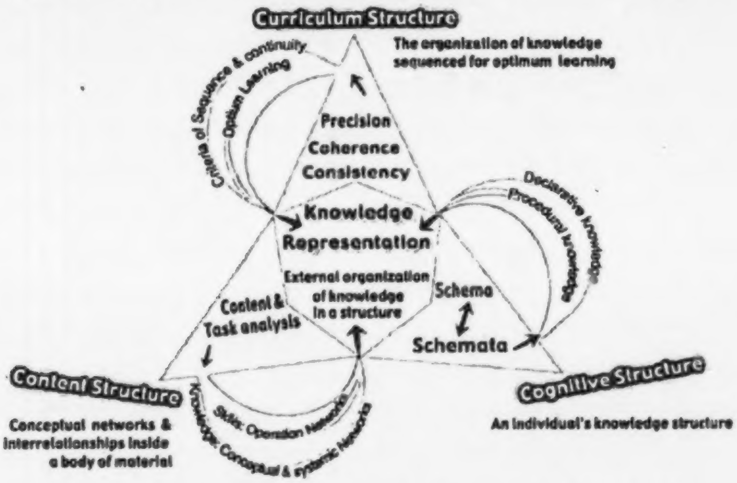
Diagnostic assessment emerges from theories of instruction, aptitude and cognition (Embretson, 1990; Glaser, 1985). It has been considered as a redesign of testing for the 21st Century. Embretson (1990) associates diagnostic assessments with dynamic testing that is defined as a measurement of learning processes by examining the consequences of instruction. Marshall (1990) and Lesgold et al (1989) point out that this assessment involves identifying causes or sources of resulting phenomena, decision making about intervention, and specifying a treatment to a problem. Instruction is changed to be adaptive and responsive to students' personal styles and conceptions (Snow and Lohman, 1993) in specified learning situations for a domain.

DCA extends the arena of diagnostic assessments from improving instruction and testing to the development of an effective learning environment. Students learn as they are solving problems for the tests (Shepard, 2000) in which they are challenged to perform. DCA re-conceptualizes assessments as an adaptive assessment-learning system. It is conceived as a coaching, learning and testing tool that is responsive to the student's individual characterizations and to the situation. It not only includes the mechanism for a) deciding characteristics of learning by examining the students' performance, b) careful investigation of the facts of knowledge acquisitions and skill mastery levels, c) formulating diagnostic interventions based on inferences of evidences, but also an agent for learning - students are coached to learn by solving the given problems that are in the form of tasks as test items of an assessment. Computerized assessment offers DCA can integrate diagnostic cognitive assessments into e-learning. It supports, directs instructional interventions and learner-centered learning, and operates the digital coaching system (a system that assist/coach learning in an electronic environment) with three models: Expert Knowledge Model, Inference Model and Student Model. In synchrony, these models interconnected with and are interdependent on each other.

1) Expert Knowledge Model

The expert Knowledge Model is built as presentations to a) explain the characterizations of how the mind of an expert works, and b) predict about what are the best strategies and knowledge an expert uses to solve problems and how these strategies and knowledge are applied within a defined circumstance.

The model plays two roles of experts in subject matter and pedagogy. As a subject matter expert, it provides DCA and the digital coaching system with the content knowledge of a domain. It also organizes and validates concepts and principles of a domain. As a pedagogical expert, the model supports the coaching activities with "pedagogical reasoning and action" (Donald, 2000, p.37) -- the capacity to transform content knowledge into forms that are pedagogically powerful and yet adaptive to students of various abilities and background (Donald, 2000). The model uses the expert knowledge and produces its knowledge representations for testing, instruction, and learning. These representations can be elucidated with three kinds of learning schemata described by Donald (1987): cognitive structure, curriculum structure, and content structure. Based on the learning schemata introduced by Donald (1987), a graphical representation of the learning schemata of the Expert Knowledge Model explains the constitution of its knowledge representations (see Figure 1 below).



Curriculum Structure
The organization of knowledge sequenced for optimum learning
Criteria of Sequence & continuity
Optimum Learning
Precision
Coherence
Consistency
Declarative knowledge
Procedural knowledge
Knowledge Representation
External organization of knowledge in a structure
Content & Task analysis
Schema
Schemata
Content Structure
Conceptual networks & interrelationships inside a body of material
Knowledge: Conceptual & systemic Networks
Skills: Operation Networks
Cognitive Structure
An individual's knowledge structure

Figure 1: Learning Schemata of the Expert Knowledge Model

As figure 1 indicates the curriculum, cognitive and content structures are interrelated with and interdependent on each other for an effective knowledge representation made for the optimization of coaching and learning. At the base of the triangle, as a support to Curriculum Structure, an expert schema, i.e. data structure for representing generic concepts (Donald, 1987), directs the operations of content and task analysis. This analysis decomposes the domain knowledge into procedural and declarative knowledge for formulating tasks as learning activities and test items. With the inputs from content and cognitive structures, a curriculum structure represents an optimization of learning by determining what steps to should be taken to a) optimize learning, b) sequence the content knowledge, pedagogical and learning activities in continuity, and c) limit or delimit the knowledge domain. While depicting how learning is measured, in order to be accountable, it ensures its learning schemata is acceptable to other experts in the domain and meet criteria of Precision (the accuracy of the representation), Coherence (the components of the representation are closely related internally), and Consistency (the components of the representation are related to existing knowledge in an overall cognitive structure) (Donald, 1987).

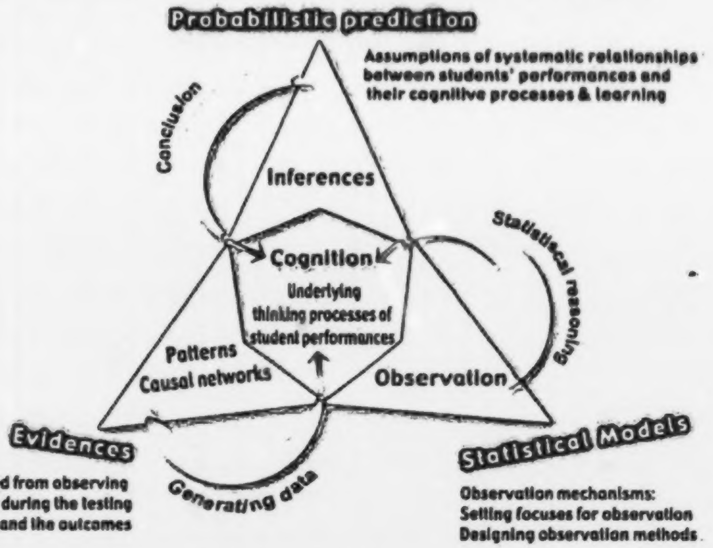
Expert models have been used in Computer Based Learning in various terminology in different forms with different purposes. Upon my observation, although this kind of model is not new, a model that integrates assessment into instruction and learning have not yet been established, e.g. BioWorld (Lajoie, 2001)

In forming the basis for developing diagnostic assessments, Frederiksen and Donin (1999) point out that conceptual knowledge and problem-solving procedures in a domain essentially derive from an expert model. A computer coach can be engineered to combine dynamic assessment of learning with diagnostic assessment of student's problem-solving processes (Frederiksen and Donin 1999). The goal for the future research will be to examine how expert models can be constructed to support diagnostic cognitive assessments.

2) Inference Models

> "In any inference task our evidence is always incomplete, rarely conclusive, and often imprecise or vague; it comes from sources having any gradation of credibility. As a result conclusions reached from evidence having these attributes can only be probabilistic in nature." (Schum, 1994, p.xiii; cited in Mislevy, 1996)

The inference models aim at making inferences about students and how knowledge and skills are acquired for the provision of guidance to student learning and adaptive instruction. Its task involves capturing, storing, and communicating the multitude of evidence resulted from inferences to the digital coaching system (DCS) for actions, and formulating the Student Model. Those tasks are harnessed by psychometrics and Bayesian Networks that take a statistical probabilistic approach to reasoning from evidence. How do they conduct the tasks? Observing the processes of testing and the test results, based on derived evidence, inferences are made from: a) a statistical psychometric model that characterizes the patterns in the data for students at varying levels of competence, b) Bayesian Networks that produce causal networks by tracing, tracking and recording student performances and strategies of problem solving during the learning process. The conclusions drawn from these inferences are probabilistic assumptions about the underlying cognitive constructs of the students' performances (Pellegrino et. al., 2001). Figure 2: Statistical Inferences shows how probabilistic prediction is concluded from inferences derived from evidences that are generated from data.



Probabilistic prediction
Assumptions of systematic relationships between students' performances and their cognitive processes & learning

Cognition
Underlying thinking processes of student performances
Patterns
Causal networks
Observation
Evidences
Statistical Models
Evidences derived from observing students' behaviour during the testing processes and the outcomes
Generating data
Observation mechanisms:
Setting focuses for observation
Designing observation methods

Figure 2: Statistical Inferences

During the process of diagnosis, on the one hand, psychometrics provides observers with task-based observations for making probabilistic inferences about the mastery level of the domain knowledge. After the identifying specific features of problems or difficulties learners have during the learning process, psychometrics examines the consequences of coaching before defining intervention characteristics. On the other hand, Bayesian Network traces, tracks, and records all the learning performances. From these accumulated processed experiences, Bayesian Networks formulates "causal structures" (Tian & Pearl, 2001) to a) interpret the effects in a defined situation and search for their causes, b) decide for intervening actions in real time, c) adapt to changes and learn from experience (Jensen, 2001) for updating diagnosis and the provision of coaching and learning guidance d) provide assessors or administrators a reliable graphical representation of instructional and learning processes that will allow them to make informed decisions (Martin, & VanLehn, 1995) .

The combined use of psychometrics and Bayesian Networks provides DCA with advances in probability-based reasoning advocated by psychometricians, such as Junker & Sijtsma (2001) and Samejima (1995) and graphical statistical modeling recommended by Pearl (2000). Mislevy, (2000) pinpoints that these advances extend the principles that underlie familiar test theory to more varied and complex inferences from more complex data.

Using psychometrics in conjunction with Bayesian inference networks diagnostic testing is considered as new testing approach advocated by Mislevy (1993), and Frederiksen, Missley & Bejar (1993). Missley (2000) states that: "Opportunities borne of new technologies, desires borne of new understandings of learning—a new generation of assessment beckons." (http://www.ncme.org/about/awards/mislevy.html). This vision is shared by others. For examples, VanLehn, Niu, Siler and Gertner (1995 a) take this approach in the research on determining a fine-grained size of knowledge representation in diagnostic testing. Junk and Sijtsma (2001) employ similar approach in the research of usability and interpretability issues for single-strategy

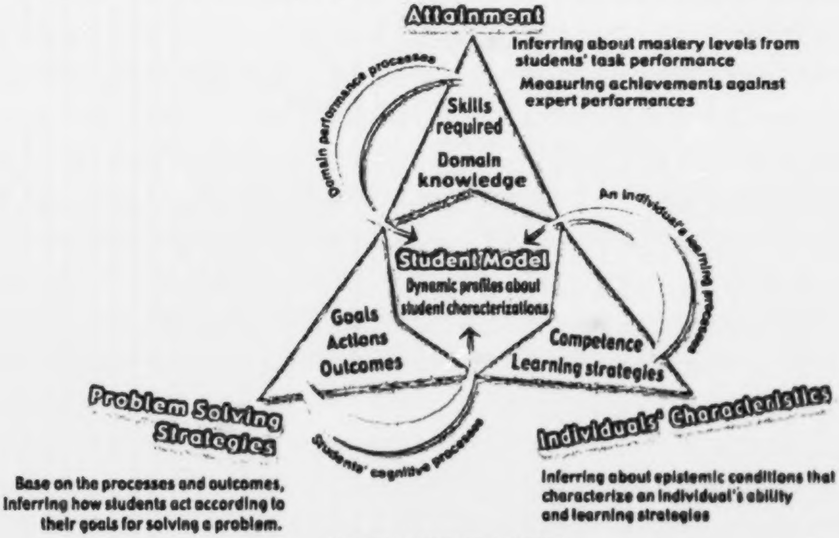
BEST COPY AVAILABLE

cognitive assessment models. Mislevy, Steinberg, & Almond (2000) also incorporated this conjunctive approach into their Evidence-Centered Assessment Design. This Inference Model of DCA can emerge as a new generation of assessment if it is supported by future research.

3) Student Model

Understanding students' knowledge acquisition and cognitive processes is essential for diagnosis. Explicit representations of these attributes are required at a level of cognitive complexity that facilitates successful performance and understanding (Kieras, 1988). However, these attributes are unobservable variables that are subjected to inferences derived from evidence (Pellegrino, Naomi, & Rober, 2001). Three kinds of reasoning are employed to construct these representations with advanced computer technologies, e.g. interactive interface, and inference tools, i.e. Bayesian Networks and Psychometrics. They are a) deductive reasoning that flows from generals to particulars, b) inductive reasoning that takes the opposite direction of from effects to possible causes and 3) abductive reasoning that proceeds from observations to new hypotheses, new variables, or new relationships among variables (Mislevy & Gitomer. 1996).

The constructed representations formulate the student model that is composed of dynamic profiles about students characterizations. The model is built as representations that a) explain the characterizations of the learners' cognitive processes, i.e. the schema b) infer, and identify the mastery level, errors, misconceptions, and knowledge gaps, c) predict about what is the best to coach the learners, d) confirm such predictions. Figure 3: Student Model depicts how the Student Model is supported, and functions within DCA.



Attainment
Inferring about mastery levels from students' task performance
Measuring achievements against expert performances
Domain performance processes
Skills required
Domain knowledge
An individual's learning processes
Student Model
Dynamic profiles about student characterizations
Goals
Actions
Outcomes
Competence
Learning strategies
Problem Solving Strategies
Students' cognitive processes
Individuals' Characteristics
Base on the processes and outcomes, inferring how students act according to their goals for solving a problem.
Inferring about epistemic conditions that characterize an individual's ability and learning strategies

Figure 3: Student Model

The student model is comprised with three components: Attainment, Problem solving strategies, and individual characteristics. Each of them addresses different functions of the model. Attainment approximates beliefs about the level of the students' competence and task performance of a domain and their interrelationships. The comparison between the students' and an expert's problem solving task performance is an indicator for identifying accomplishment, errors or misconceptions, and knowledge gaps. The resulted inferences will form the basis for generating appropriate content materials, sequencing tasks and learning units for coaching and diagnostic testing.

Next, the Problem Solving Strategies deals with particular knowledge states of individuals. It makes inferences about how students use goals to guide their actions for expected outcomes, i.e. solutions for given problems. This epistemic process involves hypothesis making that generates goal establishment, testing hypothesis leads to actions, and outcomes resulted from actions taken. Students' problem solving strategies suggest an explanation of how the students think when they learn. This explanation will pinpoint cognitive information about an individual student. It can serve as inputs to pedagogical reasoning and action.

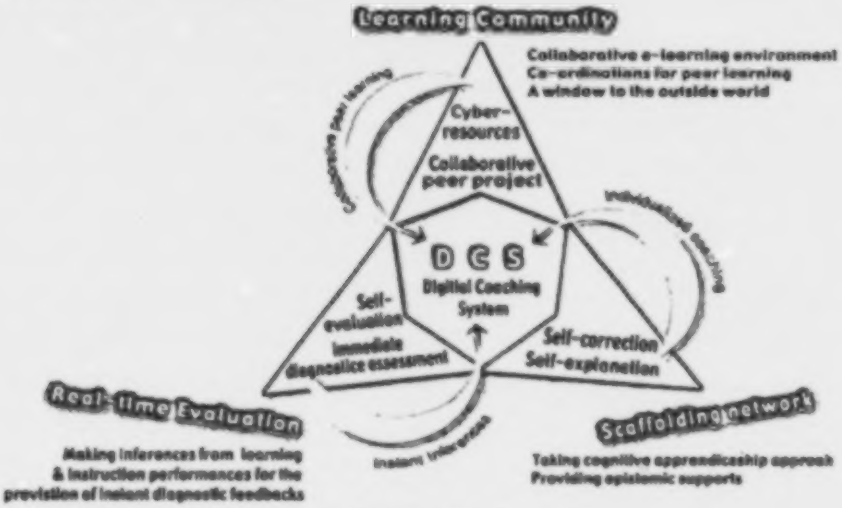
BEST COPY AVAILABLE

Finally, Individuals' Characteristics contains the schema of individual students. Based on inferences, it presents students' epistemic conditions that characterize ability and learning strategies for each individual students. It can provide information to suggest how to customize learning tasks and scaffolding, and testing that are adaptive and responsive to each student's characterizations. The knowledge about an individual's characterizations supports a) collaborative works by matching different students of different competence, b) finding the most competent peer who has good knowledge of a specific topic in a domain for peer support or peer review, c) generating modeling (examples) that map with the needs of a student for coaching d) pedagogical decision making, e.g. when and how to apply fading in which situation during the scaffolding process.

Student model is used in ITS to support flexible individualized learning and instruction, for example, SHERLOCK ITS (Lesgold et al., 1992) and HYDRIVE (Mislevy & Gitomer 1996). However, in e-learning, i.e. web-based learning systems, student model is underdeveloped, most of the so-called e-learning system is nothing more than a network of static hypertext pages. Interactivity in and adaptations to learning are limited (Brusilovsky, 1998).

DCA concerns the essential role of assessment for improving instruction, learning and testing in DCS. DCA is conceptualized as a) a tool to approximate student proficiency through the combination of detailed epistemic analysis of student performances within the Inference model with probability-based inference; b) an environment in which inferences of students' cognitive processes formulate the foundation of accurate prediction on students' proficiency and attainment. This prediction is validated by inferences derived from students performances and the dynamic Student Model; c) a crucial support to pedagogical reasoning and action. It enables DCS to provide coaching that is adaptive and responsive to the students' level of competency, and characterization.

DCA and Digital Coaching System (DCS)



Learning Community
Collaborative e-learning environment
Co-ordinations for peer learning
A window to the outside world
Collaborative peer learning
Cyber-resources
Collaborative peer project

Self-evaluation
Immediate diagnostice assessment
Self-correction
Self-explanation
Real-time Evaluation
Making inferences from learning & instruction performances for the provision of instant diagnostic feedbacks
Instant inferences
Scaffolding network
Taking cognitive apprendiceship approach
Providing epistemic supports

Figure 4: Digital Coaching System

The DCA is embedded in DCS as a monitor of the coaching activities. DCS resembles to an intelligent tutoring system (ITS) but it is not ITS because it is not merely an automated system. DCS is a) learner-centered – learners are in control of their learning, and b) dynamic – DCS has the capability to learn from its coaching experiences and observation of the learners' performances, it customizes coaching based on individual learners' needs and characterization. As Figure 5 illustrates, the system is composed of three interrelated and interdependent mechanisms: Scaffolding Network, Learning Community and real time evaluation.

The Scaffolding Network is devised to mediate individualized coaching that takes cognitiveapprenticeship approach. Based on an understanding of a student's characterization and competence, the Scaffolding Network models the domain knowledge as examples, and generates prompts and hints to stimulate and scaffold self-explanation and self-correction. The scaffolding processes are traced and recorded by the Bayesian Nets that a) supports the decision making of the Scaffolding Network, b) provides real time diagnostic evaluation of the student

BEST COPY AVAILABLE

performance and instructional intervention for self-correction of both parties, and c) co-ordinate scaffolding activities in the learning community for collaborative works.

Real-time Evaluation is a computational framework driven by Bayesian Networks with the support of an Internet server. It makes inferences from instruction and learning performances for a) generating diagnostic feedback and achievement assessments, b) updating the Student Model, and c) matching students to form collaborative work group.

Learning community is a collaborative e-learning environment for peer reviews, group projects, and posting of the students' knowledge representations, such as papers, simulations, and presentations. It is also a window for outreaching on-line resources, such as interactions with international experts, on-line conferences, and virtual libraries and journals.

These three mechanisms interact with each other and work together simultaneously. Their functions and interactions are described below in Table 1.

Pillars	Scaffolding network	Learning Community	Real Time Evaluation
Scaffolding Network	Fns: - Elicitation of knowledge from the learners - Explanation of knowledge and concept - Demonstration of skills - Generating hypothesis for testing	- Setting up reasoning tactics - Defining the problem space - Representation of knowledge - Setting up and testing hypothesis - Consolidating & reinforcing learning - Formulation of comprehension via collaborative learning, e.g. discussions	- Providing immediate advice & guidance - Recording time spent on each task - Recording &tracking learning performances as evidence - Based on evidence inferring causes and predicting the effects of a performance - evaluating & inferring learning by studying changes shown in the evidence
Learning Community	Fns: - Provisions of a) learning resources, such as on-line libraries, b) a collaborative learning environment, c) a stage for demonstrating/illustrating knowledge representations, such papers, simulations, and presentation.		
Real Time Evaluation	Fns: - Tracking and recording learning performance, - Providing real time guidance to learners, & diagnostic information to coaching during learning		

Table 1: Functions and Interactions of the Pillars Fns:Functions

Conclusion

The DCA framework described here offers an e-learning environment for coaching, learning and assessment simultaneously. As an evaluation, the framework shall be able provide objective and cognitively valid measurement of learning performance. As a diagnostic assessment, it should support instruction (coaching) and learning with reliable and valid inferences and predictions in real time. Moreover, the real time evaluation can be used to provide the coaching system and learners with diagnostic information about learners' comprehension and problem solving, including errors and misconceptions. To sum up, DCA does not only integrate assessment into instruction for the collaborative learning and problem-based learning, it also provides an innovative framework of cognitive assessment with the advanced technologies effectively for the sake of learning, not merely for using technologies. If future research can show this model can be implemented, then, it may offer one solution to the problem of assessment that is valid and reliable in measuring learning performances and learning processes for the enhancement of both instruction and learning to their best potential.

gunnar.liestol@media.uio.no

Abstract

This paper reports on a project where 3D online gaming environments were exploited for the purpose of academic communication and learning. 3D gaming environments are media and meaning rich and could provide inexpensive solutions for educational purposes. The experiment with teaching and discussions in this setting, however, proved that media complexity is not a sufficient condition for successfull online learnig environments.

Background and presuppositions

The project had two founding presuppositions, one concerning economy and popular conventions and the second related to the potential of a rich media form: (1)

1. Just a few years ago several online gaming environments emerged on the market with great success. It soon became obvious that 3D-based online games made it possible to conduct extensive communication and collaborative action in relatively rich graphical environments on the Internet. Thus an interesting opportunity arose in the combination of ICT and learning: Instead of developing expensive 3D-environments from scratch for specific learning purposes it should be possible to exploit existing 'off the shelf' game software. This would mean that we used the online gaming environments contrary to their intention, so to speak, not for leisure gaming but for organized learning. Would it be possible to intervene in such environments, not for the sole purpose of learning the game, but for learning in general? If this assumption was correct time and money could be saved, and at the same time one could benefit from some of the popular interface- and userconventions already developed within game genres, conventions which are often related to problem solving and learning.

2. My interests in 3D online gaming environments was not primarily motivated by their game-structure, but by the potential of 3D itself, as a form of representation. 3D, we might say, is a new kind of sign or sign system. Dynamic and navigable 3D documents is the inherent information type of the computer as a medium, and thus different from more traditional information types such as writing, still images, sound and moving images, which all have emerged within analogue, non-computerized media. Dynamic 3D has the

fascinating feature that it is capable of re-presentation and may include any of the traditional information types (Liestøl 1999). 3D is situated on top of a hierarchy and embraces the underlying and less inclusive information types. At the bottom of this hierarchy we find writing, which is not capable of representing any other information type. The still image on the other hand is capable of including writing. Further, moving images may include both writing and still imagery. Audio constitute a separate, independent system of various information types and may be synchronized with moving images as in film and television. However, I would argue that inclusion of audio in another information type is only made possible when we operate with sources of sound 'inside' virtual spaces, that is inside dynamic navigable 3D spaces. Thus, 3D documents may include all traditional information types (and more), and as representational forms they serve as places where other information types may appear and interact as combined and integrated units. Given these features the potential complexity of expression and meaning in 3D environments is beyond comparison in the history of media and representation, and consequently it should be of relevance for communication and learning. My interests were particularly focused on how the interplay between information types could be exploited. The following assumption forms the basic motivation for the experiment reported and discussed in this paper: Because 3D is the all-inclusive representational form it should — in theory — be better suited for the purpose of communication (and learning) than for example purely verbal environments like MUDs and MOOs.

Selecting an environment

In order to find a suitable 3D online environment to test this hypotesis several online games and gamelike environments were examined: *Diablo*, *Ultima Online*, *Online traveller*, *Virtual Places* and *Everquest*. (2) To brake with the intentional purpose of the established online environments, it was important for us as users to be able to make imprints in the environments, for example by means of imported custom made graphics. Common to the popular online games, however, where the fact that they exclusively were open to verbal and navigational input, and that the user only to a very limited extent was capable of 'fitting out' the environment (selection of avatar elements, that is the user's graphical representation in the 3D environment). It was not possible in any of the games to import externally produced graphics. This, of course, would limit our expressive means, like a classroom without a blackboard. After experimenting with and evaluating various systems available, *Active World* (AW) was selected. (3) AW is not a traditional online game, but it supports import of various graphical elements (images, movies etc.) and thus would meet our needs for an environment rich on expressive means.

Format/genre

Our activity in *Active World* began by testing the basic functionality. The purpose was to decide which kind of communicational formats or learning genres could be realized in this environment. The initial idea was to recreate some kind of roundtable discussion/seminar where every participant could view all the other participants, in order to communicate both by means of (written) verbal utterances and 'body' (avatar) behaviour. All participants should be equally represented and positioned in the setting, nobody was supposed to have neither priviliged perspective nor functionality. The purpose was thus to recreate and reconfigure a format inspired by traditional oral forms of academic communication, such as the seminar and the colloqvium.

The investigation of the conditions for creating a roundtable configuration developed into a project of problem solving itself. After a process of trail and error the participants experienced some basic constraints for this kind of mutual communiction in the chosen environment. In order to fulfill the egalitarian premisses and for everyone to see each other, the number of participants, unfortunately, had to be limited to three due to the restricted view of the 'wideangle' perspective. The result was dissapointing and the idea of recreating the 'colloqvium' was abandoned. We were forced to use a configuration that was sequential and a mode of communication that had a one-way, broadcast-like structure. The traditional position in the auditorium/classroom with the teacher in front of the students was therefore chosen.

The interface in AW consist mainly of two windows: one for graphics that represents the graphical 3D -environment, and one for chat where the exchange of words and sentences are shown in temporal sequence as they are produced. Below the dialogue window there is an input area, where each and every participant write their messages. In the graphical window (into the 3D soace) the actual utterances of the participants are shown as 'bubbles' based on comic strip conventions. The dialogue is displayed both isolated in the chatwindow and intergrated in the graphic environment. On the left side of the picture there is a list of some of the hundreds of different accessable AW worlds. In addition there are several pre-programmed functions related to how avatars move and 'behave' in relation to others. AW also presents opportunities for direct linking to web-pages which may be opened in separate windows.

The Session

The session was conducted as a 'traditional' academic lecture. The topic was 'Brian Winston's theory of media innovation'. (4) A series of five slides were produced in advance and mada available in sequence as visual support for the verbal presentation. At

any time the students were invited to ask questions etc. by showing a (double) sign: waving their hand and at the same time typing the sign '*'. Then the teacher (the author of this paper) presented the talk while at the same time showing the various slides on a large blackboard next to him. Several of the comments and explanations of the slides were written in advance and copied to the text field. Due to the coarse of the discussion many of the ready made sentences had to be rewritten and used in a different order.

The talk lasted for approximately 30 minutes, interrupted by questions and discussion. After the presentation we commented upon and discussed our experiences during the session. We all agreed that the session worked well and that the outcome of the talk, in regard to the combination of verbal presentation and use of illustrations, were comparable to a traditonal lecture. Further, it was argued that the spatial dimension added to the experience of relating to persons in different positions, particularily when compared to verbal chat.

However, several of the participants noted that the attention directed towards the 3D graphic window was constantly interferred by the need to look at the chat window. As the dialogue developed, and to catch up with who said what and in which order we more and more focused on the information in the verbal only chat wndow.

Conclusion: Ffgurative versus Verbal

BEST COPY AVAILABLE

It was not surprising to find that the participants had a fascinated experience and felt some kind of surplus gain from being represented 'inside' the navigable 3D space. What was rather surprising, though, was that the experiment clearly demonstrated that the written verbal information dominated the process, even though the graphical and figurative aspects had high priority. One of the main premisses for the investigation had been the potential of extended complexity and richness of meaning in 3D-environments. This premiss was explicitly employed in the experiment: Only the graphical window allowed a view of the slides (the central element of the representation) parallell to the written information, while the chat window below only displayed the verbal information. Why did the verbal representation get more attention by the participants, in spite of the fact that the graphical window showed a more complex content, and inspite of the expressed surplus value of spatial positioning? I think the answer to these questions consists of two parts:

1. The chat-convention is supported by a well-established practice from other applications, such as different forms of IRC, and dialogue in verbale solutions. Most of the participants are experienced with verbal only chat-solutions, thus 'bubble' based chat in 3D-displays is a rather new phenomenon. But this cannot be the full explanation.

2. Even if 3D in the opening of this paper was described as a potentially richer environment and form of representation compared to other types of information, it passes on constraints that other and seemingly simpler forms of communication does not have or have defeated. The preliminary development of conventions exploited in 3D have a strong focus on realism, driven forward by the development of the computer game tradition. The recreation of the real world in a representation with continuum in space and time, the highest possible resolution and faithfulness according to the law of physical and visual reality, seems to have the highest priority. This kind of priority does neither gain the user-friendlieness nor an efficient handling of information. In IRC the dialogue is saved as a linear sequence and the structure is therefore easy to navigate. Thes stored conversation also becomes a collective memory. 3D-surroundings lack both these dimensions. Assuming the demand on spatial realism, 3D has so far no convention for displaying history or stored actions and events. 3D-environments are not able to supply the user efficiently with information along the temporal axis. The bubbles do not indicate succession, and it becomes difficult to distinguish between question and answer. The relationship between utterances are disrupted by the spatial organisation.

This shows that for the purpose of communication the illustration or display of temporality is more important than spatiality, in spite of the fact that the 3D environment consists of both unique and more diversified and meaningrich information. Wheather this can be explained as a temporary fenomenon due to an immature medium, is not easy to say, but it indicates the efficiency of verbal communication. (5) And that is worth thinking about when one consider the high priority multimedia currently has.

Notes:

1. This project was part of the Computer Games and Learning project at the Department of Media and Communcation, University of Oslo 1998-2001, funded by ITU <www.itu.uio.no>

Abstract: This paper provides a holistic approach to viewing the e-learning phenomenon from a theoretical perspective. It constructs a framework for e-learning development by drawing upon the literature for learning models, knowledge management and utilization of technology for electronic education. In so doing, it conceptualizes the continuous and progressive phases of infrastructure, infostructure and knowledge-structure integration to leverage Information & Communication Technologies (ICTs) more efficiently and effectively for the delivery of a holistic learning experience. By applying this developmental model, the e-learning practitioner possesses an evaluative tool to enable an upward spiral process of continuous feedback and improvements to the e-learning architecture and contribute more strategically to the development of a total learning experience. For the learner, the model generates strategic value from knowledge creating and sharing activities.

Introduction

Decisions to embrace the use of learning technologies for managing and working in the new digital and knowledge economics have fundamentally changed global business and social landscapes. With this increasing emphasis on a knowledge-driven e-based society, learning has been given center stage for its potential in developing the individual through instilling a proactive learning attitude essential for dealing with the dynamism of a complex environment (Sangster, Maclaran and Marshall, 2000). Educators such as Rosenberg (2001) have advocated the merger of Infocomm Technologies (ICT) with educational. philosophies to create an integrative virtual learning or "e-learning" environment. Most research in the area of e-learning has focused on the pivotal role of ICT in the process of learning (see Davies, 2000; Lee, 2000; Collis et al., 2000). Others dismissed such emphasis on the technical aspect of elearning and instead, contended that technology serves merely as a facilitator. Though insightful, these arguments exist on extreme ends of the e-learning continuum and represent a constrained perspective of an otherwise dynamic field. Considering the extensive implications of e-learning on the digital economy, this paper suggests an alternative holistic approach of viewing the e-learning phenomenon, resulting in a framework for e-learning development. The proposed model will draw upon available literature on learning models, knowledge management issues and the utilization of technology for electronic education.

E-learning: Integrating Learning, Knowledge and Information Technology

E-learning is gaining momentum in the managerial and academic arena. Organizations are actively searching for effective e-learning strategies whereas researchers have begun their initial explorations into the definitions and perspectives of the e-learning phenomenon.

Distance Education

One prevalent definition of e-learning is the use of assisting technologies to create educational opportunities without regards to both time and space (Jarvis, 1993). This emerging model of learning whereby learners can access the educational content "anytime, anywhere" has been commonly coined as "distance education" (Mangan, 2001). Distance education has been well received among business organizations and learning institutions for its flexibility in delivering an equilibrium between the need for knowledge acquisition and the fragmented time schedule of individual learners. For example, studies conducted by Pitcher et al. (2000) have demonstrated that substantial cost savings and efficiency can be obtained from the widespread use of distance learning in higher education.

With the progression in ICT, distance education has manifested into various forms, ranging from virtual classrooms (Hiltz, 1992) to the formal delivering strategy of telelearning (Collis, 1996) and the electronic platforms of cyberschools in the new knowledge society (Jones, 1998). Mangan (2001) has intuitively summarized these developments by classifying distance learning into computer-based training (CBT), videoconferencing and Web-based training (WBT). Others such as Sanderson and Scivier (1998) advocate the alternative use of computer-mediated communication (CMC) as the main component of virtual seminars to imitate conventional forums by simulating a digital collaborative learning environment. However, Veen et al. (1998) questions the effectiveness of such virtual seminars. In response, Tansley and Bryson (2000) championed the need for corresponding infrastructural and social changes in order to ensure the overall success of virtual seminars. Furthermore, Persico and Manca (2000) included customizability as a dimension to be considered in designing CMC systems so as to provide a simple and easy interface that is user-friendly and configurable in accordance to different learning principles.

More recently, the popularity of the Internet has attracted its share of advocators, who are quick to propose the W^3 as becoming part of the mainstream infrastructure in distance learning (Cole, 1998; Houlder, 1998). Indeed, the W^3 is hailed as the next revolution in education because of its time and geographical independence; its ease in delivering and updating information; its improved interactivity; its user-centric environment and its capacity to accommodate an almost infinite number of learners (Marchionini and Maurer, 1995; Kapur and Stillman, 1997; Lee et al., 1997; Mudge, 1999). Nevertheless, despite the Internet's ability to transcend time and space, studies by Thomas (2000) have proved that students in practice still prefer to maintain some form of physical contact. Moreover, the Web is often criticized for overloading the user with excessive and irrelevant information (Nielson, 1995). As such, Grabinger and Dunlap (1995) advised that though it is imperative to have the accessibility to the richness and variety of materials available from the Internet, the specific learning goals should not be overlooked.

Though evidence points to distance learning as an efficient technique for offering high quality education for students in any geographical locations (Burke and Gill, 2000), findings by Al-Kodmany et al. (1999) have suggested that technology should supplement traditional teaching methodologies rather than supplant them. Hence, it is necessary to look beyond the technical elements of distance education and examine more closely how such initiatives can be effectively integrated into existing learning philosophies.

Learning Models

The conventional learning model originates as an objectivist model, in which a reality exists and experts instruct individuals of that reality (Belanger and Slyke, 2000). However, the emergence of learner-centric approaches such as constructivism and socio-culturalism has overshadowed conventional ideas and lent weight to the empowerment of individuals to take charge of their own learning environments. Learning theories such as andragogy (Knowles, 1984), minimalism (Carroll, 1990; Van der Meij and Carroll, 1995), experiential learning (Rogers, 1969; Kolb, 1984) and action learning (Revans, 1980) have established strong links between learning and the practicality of doing.

Although these constructs of learning may differ in their perceptions towards the provision of education, they share two common objectives: to emphasize the value of learning by doing and the importance of ensuring an enriching learning experience for the learners. Moreover, as highlighted by Alavi (1994), learning is most effective when it involves the process of problem solving through collaborative brainstorming. With the improved connectivity and increased interactively of ICT, these commonalities will prove to be pivotal to the delivery of a holistic learning experience for the students.

A comparison between the different learning philosophies is summarized in Table 1 below:

Learning Model	Advocators	Characteristics
Experiential Learning	Rogers, 1969; Kolb, 1984	- Application of knowledge to address the specific needs and requirements of the learner. - Learning is primarily focused on problem solving and the learner is totally involved in and has control over the nature and direction of the learning experience
Andragogy (Adult Learning)	Knowles, 1984	- Learning is facilitated when adults learn experientially in a self motivated, problem-solving approach to grasp topics of immediate value.
Minimalism	Carroll, 1990; Van der Meij and Carroll, 1995	- Describes a framework for learning that emphasizes the value of unobtrusive learning content in facilitating self-directed learning activities.
Constructivism	Tobin and Tippins, 1993; Leidner and Jarvenpaa, 1995; Brandt, 1997	- A learning process whereby knowledge is created from using what is known to find sense in experiences. - New information gathered through experiences is integrated with existing mental models to result in expanded, more complex mental models.
Cognitive Information Processing	Bovy, 1981; Leidner and Jarvenpaa, 1995	- A learning model, which proposes learners as having their own individual learning frame of references and only information that has been processed can result in actual learning. - Individuals tend to rely on their prior knowledge obtained from their mental models of the particular domain of expertise to process new information.

Table 1: A Comparison of Learning Models

Apparently, from the table, learning is most efficient when the learning environment is customized to meet the specific needs of individual learners and most effective when learning is facilitated through collaborative problem solving. In other words, learning efficiency is enhanced when learners require the least effort to access the learning facilities such as in the situation where e-learning is accessible "anytime, anywhere" (Rosenberg, 2001), making it convenient for learning to occur within fragmented time schedule and thus conserving substantial time resources. Effectiveness on the other hand, refers to the capacity of learning to generate value for the learners and this can be best addressed when learning is seamlessly integrated into the solution of learner-centric problems such as the case where e-learning can provide for collaborative infomation and knowledge sharing activities tailored towards topic-specific discussions. Hence, the merger of efficiency and effectiveness in learning completes the universe of an enriching, directional learning experience and embodies the fundamentals of knowledge creation, retention and utilization. It is, therefore, imperative to examine the integration of knowledge management into the learning process and understand how they can complement each other in the provision of an e-learning future.

Knowledge Management (KM)

As pointed out by Nonaka (1991), the management of knowledge plays a pivotal role in the heart of any organization's human resource strategy. Nonaka (1994) devised what he termed as the "Spiral of Knowledge", which explains the creation of knowledge through conversions between tacit and explicit knowledge. Explicit knowledge refers to the visible, expressible form of information that can be transmitted in a formal, systematic manner whereas tacit knowledge is often associated with intangible individual experiences. Nonaka proposes that there are four different modes of knowledge conversion and for each of these modes; Nonaka (1994) attaches a method of knowledge creation. Socialization is the activity that binds individuals from differing backgrounds and experiences to create tacit knowledge because the mere transfer of information would be meaningless without some form of common understanding (Nonaka, 1994). However, this tacit knowledge must be transformed into explicit knowledge through the process of externalization such that the knowledge can be organized in a logical, systematic format, which can be easily conveyed and comprehended to a wider audience. When different bodies of explicit knowledge are combined through the use of social processes, the reconfiguration of existing information through sorting, adding, re-categorizing and re-contextualizing can lead to the creation of new explicit knowledge. Internalization is the last mode of knowledge conversion within the cycle and involves the creation of tacit knowledge from explicit knowledge whenever individuals make use of the shared explicit knowledge as a basis upon which to broaden, extend and reframe their own tacit knowledge base. By injecting ICT into the fundamental knowledge

BEST COPY AVAILABLE

architecture that supports these knowledge-creating activities, the learning experience can be effectively enhanced and strategize.

The "learning organization", as described by Prokesch (1997), is one such example that has successfully made ICT an integral component of knowledge management activities. In essence, the learning organization is structured to leverage knowledge by replicating it efficiently amongst the individuals with the use of ICT such that each participant is not learning in isolation (i.e. knowledge sharing activities are facilitated through a single information infrastructure). This notion of a learning organization is also shared in the works of Leonard-Barton (1992), who further emphasizes the importance of empowering individuals so that they may have the self-confidence, freedom and motivation to continuously solve problems and learn to reinvent in the process. In this way, the level of knowledge can be homogenized throughout the community and, thus, bridging the widening knowledge gap.

Communities of Practice (CoP) is another management strategy that focuses on the effective sharing of knowledge to generate strategic learning value (Wenger and Snyder, 1999). CoP refers to groups of people informally bounded by shared expertise and passion for a joint purpose. A community of practice may not have an explicit agenda and within it, people share their experiences and knowledge in free-flowing, creative ways that foster new approaches to problems. Hence, a familiar, conducive learning environment is fostered within CoP that encourages the creation of new knowledge through collaborate learning and develops the individuals' ability to build and exchange knowledge.

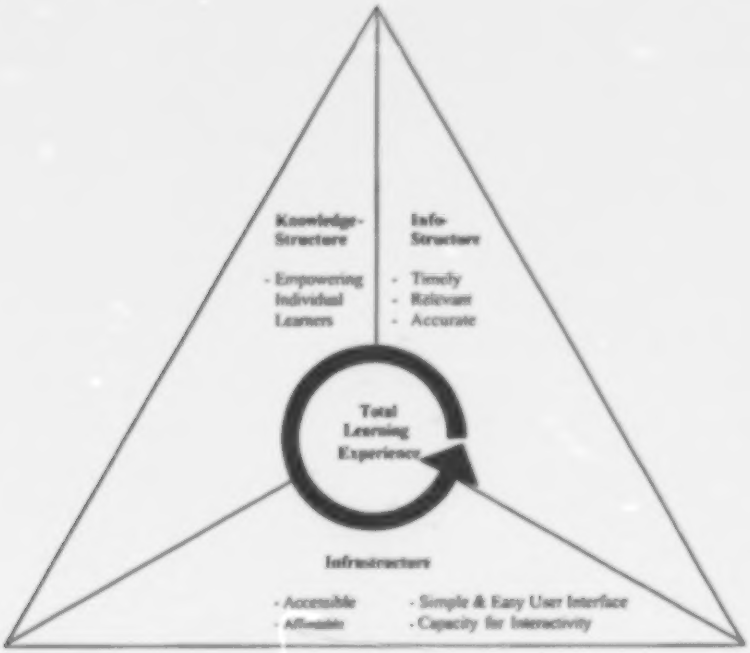
From the previous discussion, e-learning can be perceived to be one of the following:

- *The Integration of Technology into the Process of Learning.* In this case, e-learning is explained as an innovation of technological advancement and dismisses the intangible qualities of the dynamic learning process for greater efficiency in information diffusion capability. Nevertheless, literature from such technical perspectives of viewing elearning supplies insights that can be adapted to characterize the **technical infrastructure** required for an effective e-learning experience.
- *The Extension of Student-Centric Learning Models onto Virtual Environment.* This practice is simply concerned with the wholesale shoveling of traditional learning models onto new communication mediums and does not consider the possibilities of innovative learning opportunities that are present through the marriage of ICT with conventional educational philosophies. A true learner-centric model does not perform the mundane task of providing stagnant educational material through new communication media. Rather, by having students as the center of attention, e-learning must be able to appreciate individual learning requirements and supply educational content that can best match those needs. In other words, any learning information provided over the underlying infrastructure should be timely, accurate and relevant; the core of a **sound infostructure**.
- *The Management of Knowledge Activities using ICT.* This area of study only focuses on the issues of knowledge creation and sharing but does not provide an explicit link between the knowledge activities and the underlying information structure (infostructure) that is required to support these activities. Given the dynamism of the new economy, the value and lifespan of any form of knowledge is ultimately decided by the characteristics of the information upon which the knowledge is obtained. Moreover, despite the fact that existing knowledge literature is based primarily on organizational studies, it does not imply that these knowledge practices cannot be adopted on an individual learner level. Such organizational knowledge initiatives represent viable options for e-learning to generate strategic value for the individual learner as well. The **knowledge-structure** examines the ways in which knowledge practices can be applied to enhance learning on a larger social scale.

Nonetheless, each of the above perspectives represents just one dimension from which to examine an otherwise multi-faceted discipline and as such e-learning should be considered from a more holistic perspective. The discussion section provides an e-learning model that encompasses the various aspects of ICT, learning models and knowledge management into a singular educational architecture.

Discussion

From the discussions, a holistic view of e-learning would then be the integration of the above three dimensions into a unified strategic educational framework (i.e. e-learning involves the leveraging of ICT to deliver efficient and effective learning to individuals so as to generate strategic value from knowledge creating and sharing activities and in so doing, provide a *Total Learning Experience (TLE)* to the learners). Specifically, the e-learning developmental and evaluative framework should comprise three continuous and progressive phases: the *infrastructure*, the *infostructure* and the *knowledge-structure* (see Figure 1).



Knowledge-Structure
- Empowering Individual Learners
Info-Structure
- Timely
- Relevant
- Accurate
Total Learning Experience
Infrastructure
- Accessible
- Affordable
- Simple & Easy User Interface
- Capacity for Interactivity

Figure 1: Total Learning Framework

Depicted in the above diagram, Infrastructure refers to the supporting technologies upon which the subsequent info- and knowledge-structures rest. It represents the foundation of e-learning by clearly defining the characteristics of ICT that should be present to facilitate a total learning process:

1. The technology should be accessible to all interested parties. Accessibility in learning is not constrained to pure geographical proximity; it is also the ability to transcend time in the delivery of learning content. As suggested by Rosenberg (2001), the requirements of learners with different time restrictions can be best met if learning can be done "anytime, anywhere". In this respect, the improved connectivity brought about by advancement in ICT acts as a convenient platform for educators to efficiently disseminate their materials to audiences of a greater reach.
2. In addition, the user interface, through which the educational content is being delivered, should be simple to navigate and easy to master. As suggested by the minimalism learning model, navigation is an important factor of effective learning because even if the educational materials are made readily available for the learners, their intended purpose will be defeated if the learners find difficulties in locating them. The degree of complexity in mastering the use of the delivery mechanism is another area of concern. If the technicalities involved in receiving the learning content require a substantial level of technical competence, then potential learners may be deterred.
3. The third characteristic of an effective learning infrastructure is the affordability of the supporting technologies. As evidenced in the study by Carville and Mitchell (2000), technologies such as video conferencing exist as "a relatively inexpensive way of providing remote students with the nearest thing to 'face-to-face' teaching". This observation bears practical implications for e-learning since the value of e-learning is derived primarily from participative learning and as such, it shares similar characteristics with the Internet in the sense that the degree of benefits to be reaped from the learning process is directly proportional to the level of participation. Hence, a cost-effective infrastructure for the learners is an essential

condition for e-learning to maximize its potential in the creation of knowledge by encouraging critical mass participation.

4. Finally, the technical infrastructure for e-learning should possess the capacity for significant interactivity. Interactivity among learners is not a new trend in learning. Since the birth of student-centric education, classroom discussions have already been incorporated as an integral part of the curriculum and in recent years, collaborative brainstorming has become a recognized technique in problem-centric learning (Alavi, 1994). However, interactions of such have long been constrained by the need for physical presence and can only occur on a fixed or limited scale. With the latest changes in ICT, interactivity in e-learning can now take place virtually at almost infinite capacity, which in turn has contributed substantially to expansions in the scope of educational discourses.

Despite an effective infrastructure, a TLE would not have been possible without an equally effective infostructure. Infostructure is the normative structure of information for e-learning that builds on the foundations of infrastructure and acts as the facilitating architecture for the ultimate aim of knowledge creation. In particular, the infostructure defines the characteristics of educational content that will blueprint an efficient and effective learning process:

1. Firstly, the learning content of an effective educational process should always be timely. As illustrated by Rosenberg (2001), speed is the essence of the digital society and time can either be a competitive asset or liability. In other words, the lifespan of information has been substantially shortened with rapid progression in ICT and learning can no longer be a dormant process. In fact, long gone are the days when educational content can remain stagnant for years to come as information is updated constantly. Hence, a crucial component of an effective e-learning framework would be the timeliness of the information being disseminated to the learners.
2. The second aspect of an efficient infostructure would be the relevance of the learning materials. In an age where information is the social currency, learners are often bombarded or even confused by the overwhelming amount of information available from multiple sources. Termed as information overload, this chaotic phenomenon posed a threat to effective education because learners' resources would be wasted in sifting out the required information. It is, therefore, in the basics of e-learning to understand the learners' objectives through interactions and then supply the relevant learning materials that best match their expectations and specific needs. In essence, the relevance of the learning information is associated to the learning model of cognitive information processing (Bovy, 1981; Leidner and Jarvenpaa, 1995) where it is commonly believed that learners possess their own individual perceptions of what constitutes relevant learning information and as such, learning is most effectively managed in e-learning since the same educational content can be effortlessly and inexpensively personalized to suit the needs of individual learners.
3. The third and last characteristic of an e-learning infostructure is the accuracy of the educational content, which must be ensured in the learning process. Similar to the case of relevancy as discussed above, the huge and disorganized flow of information places a question mark on the value of every piece of information and erodes the confidence of e-learners. As such, for e-learning to take off, the accuracy of information contained within the pages of the learning materials should not be compromised. Moreover, constructivism (Tobin and Tippins, 1993; Leidner and Jarvenpaa, 1995; Brandt, 1997) assumes the creation of new knowledge as the integration of new information into existing knowledge base and hence, underlining the dangers of misguided information towards the expansion of an individual learner's knowledge base.

Once the supporting infra- and info-structures are in place, it is now viable to develop the knowledge activities (knowledge-structure) that support the total learning process. As opposed to the previous two phases, the knowledge-structure is not a tangible process with definitive characteristics. Instead, the knowledge architecture emphasizes the cultivation of an inherent knowledge management mentality within each learner so as to actualize the full potential within each individual. This knowledge-structure builds upon the physical learning foundations and considers the mannerism in which such mentality can be realized in the very nature of individual learners. Typically, empowerment of the individual is derived from the cultivation of such thinking to create the self-confidence, freedom and motivation that is necessary to continuously solve problems creatively and to reinvent in the process (Leonard-Barton, 1992). However, empowerment is not attained simply by delivering educational content to the doorsteps of the learner through electronic media; rather, it is the induction of a proactive approach to the learning process and it can only occur through the realization of an effective infra- and info- structure. Without connectivity to a wider and more diverse group of learners through the use of ICT, the individual would be synonymous to that of an everyday classroom student. It is only with the accessibility of a much greater reach brought about by ICT that individual learners are truly empowered to interact freely with one another. Furthermore, empowerment is not truly complete without the sound and reliable supporting role of the infostructure. The exchange of information during interactions must obey the characteristics of the infostructure presented above in order to solve problems not only creatively, but also timely and accurately.

Summarizing the above discussion, e-learning can be conceived to be an unbiased collaboration of the Infrastructure, Infostructure and Knowledge-structure to deliver a TLE to learners. Each of these phases possesses definitive characteristics that act as the governing boundaries for the development of a TLE and together, these characteristics constitute an evaluative framework for e-learning practitioners. As illustrated in the model, the evaluative analysis is an upward, spiraling process of continuous improvements to the e-learning architecture, which are governed by the dynamics of the three structures so as to realize the full potential of a TLE. Moreover, it should be emphasized at this point that the evaluation of any e-learning development can be performed at any phase of its development, be it the infrastructure, infostructure or knowledge-structure, so long as the characteristics of the overall e-learning architecture are fulfilled.

Conclusion

The total learning framework presented is a preliminary model for the practical development of e-learning. By projecting the framework as a combination of three spiraling structures and defining their essential characteristics, the total learning model serves as guiding principles for practitioners in the development of e-learning modules. However, considering the dynamism of economic and social changes, the model is never intended to be fully comprehensive. Full empirical studies are required to support and expand on this model so as to fine-tune it to make it applicable for the effective management of e-learning initiatives. An important emphasis of this paper is the subtle but crucial message that learning is never meant to be a mono-dimensional and static process. Instead, it must feed on the capabilities of technology and the limitless potential of the mind to develop and expand into a strategic, creative routine of society.

Designing ICT Training Material for Chinese Language Arts Teachers

Janet Mei-Chuen Lin, Cheng-Chih Wu and Hsiu-Yen Chen
Department of Information and Computer Education
National Taiwan Normal University
Taipei, Taiwan
mjlin@ice.ntnu.edu.tw

Abstract: The purpose of this research is to tailor the design of ICT training material to the needs of Chinese language arts teachers such that the training they receive will be conducive to effective integration of ICT into instruction. Eighteen experienced teachers participated in a Delphi-like survey that comprised a series of four questionnaires. They were asked to describe the professional tasks they routinely performed. Their responses were compiled into a list of 90 task items. Each item was then associated with one or more hardware/software tools that teachers need to learn to perform that task more productively. A restructuring process reduced the total number of items to 67. There will be one training unit developed for each of the 67 items, with each covering certain hardware and software features that we specified. We have developed six training units in the tryout phase with the help from five teachers. These units are characterized by their subject-specific contents.

Introduction

Teacher training in information and communications technologies (ICT) often uses "general-purpose" or "one-size-fits-all" training material for all teachers. The underlying assumption seems to be that all teachers should be able to benefit from the same set of training material regardless of difference in content areas they teach. This probably results from the fact that most training courses often focus predominantly on general skills in common application software rather than on effective integration of ICT into subject teaching. Researchers have pointed out that dipping staff members in training workshops that emphasize provision of ICT skills is not an effective way to get them to use the technologies, much less so to guarantee that they can become innovative integrators of technology into the curriculum (Hannafin, 1999; Hoffman, 1997; Lawson & Comber, 1999).

Different subject areas vary widely in their content knowledge as well as pedagogical methods. It follows that ICT may most likely be used in different ways and for different purposes by teachers of different subjects. Training programs should, therefore, be tailored to teachers' subject-specific needs. Such programs are possible only if training material could be designed based on a detailed analysis of the pedagogical practices of each subject and on a thorough understanding of what teachers really want ICT to help them. The research reported in this paper is a first attempt and an on-going effort to attain this goal. In the remainder of this paper, Section 2 is a description of our multi-round questionnaire survey and the result we got; then, in Section 3, we explain how we mapped the 90 task items to 67 training units. In the end are the conclusions and a sketch of our future work.

The Questionnaire Survey

This research had been conducted using a modified form of the Delphi technique (Cyphert & Gant, 1971; Weaver, 1971). Eighteen Chinese language arts teachers were invited to participate in the questionnaire survey. All of them met the following two criteria that we set for selecting participants: a minimum of 10 years' experience in Chinese language arts teaching and possession of adequate basic skills in common application software (including word processors, presentation software, and Internet tools such as web browsers and email software). They were from nine different secondary schools. Seventeen of them were female and one was male. The typical Delphi procedure of one multi-round questionnaire was modified into a series of four different, though highly coherent, questionnaires in this study. We preserved the essence of the Delphi technique by assembling the responses of each round and reporting them back to the respondents in the subsequent round for elaboration and/or revisions. The four questionnaires were mailed to the participants between August and November 2001.

The first-round questionnaire contained 16 open-ended questions, as shown in (Tab. 1). The first seven questions focused on the five major aspects of Chinese language arts instruction (i.e., reading, writing, Chinese calligraphy, oral presentation skills, and additional reading instruction). Respondents were asked to describe about the pedagogical practices of Chinese language arts instruction and the problems they had observed. Then we posed six questions related to how teaching aids had been used in classroom teaching. The remaining three questions concerned other routine duties that Chinese teachers were usually required to perform.

	Question
1	According to the official curriculum guidelines, Chinese language arts instruction in the secondary schools is supposed to cover the following five aspects: reading, writing, Chinese calligraphy, oral presentation skills and additional reading instruction. Please describe what is being taught in each of these aspects and the percentage of total lecture hours allocated to each.
2	Please describe common pedagogical practices of *reading instruction*. What do you think are the major problems of current practices?
3	Please describe common pedagogical practices of *writing instruction*. What do you think are the major problems of current practices?
4	Please describe common pedagogical practices of *Chinese Calligraphy instruction*. What do you think are the major problems of current practices?
5	Please describe common pedagogical practices of *oral presentation skills instruction*. What do you think are the major problems of current practices?
6	Please describe common pedagogical practices of *additional reading instruction*. What do you think are the major problems of current practices?
7	What are major difficulties faced by Chinese language arts teachers with regard to classroom teaching?
8	What are the common teaching aids used by Chinese language arts teachers? How often are they used?
9	How effective is the use of teaching aids in enhancing classroom teaching?
10	What are students' feedback on the use of teaching aids in Chinese language arts instruction?
11	What are the major difficulties faced by Chinese language arts teachers when they try to use teaching aids?
12	What teaching aids do you think that Chinese language arts teachers need most?
13	How do Chinese language arts teachers prepare for classroom instruction? What tools do they use most often with regard to preparatory work?
14	Other than classroom instruction and preparatory work, what are other tasks that Chinese language arts teachers' are required to do on a regular basis?
15	Among the various professional tasks carried out by Chinese language arts teachers on a regular basis, what tasks are thought to be most demanding on teachers' time and effort?
16	What do you think that the computer can do to ease Chinese teachers' teaching job?

Table 1: Questions in the First-Round Questionnaire

We compiled the participants' first-round responses and presented the result in the second round questionnaire for further elaboration and/or revisions. The second-round result was then organized into a list of 90 task items. Among them, 55 items were directly connected to teaching, including preparatory tasks (e.g., gathering information for lesson plans), classroom teaching (e.g., teaching formal letter writing), and after-class tasks (e.g., grading exam papers). The remaining 35 items were mainly administrative (e.g., classroom management) and communicative (e.g., mentoring) tasks. (Tab. 2) shows the first 12 teaching-related items that were grouped under the section of "Preparatory Tasks for Lectures."

1.1	*Preparatory Tasks for Lectures*		*Rating*				
	1.1.1	Preparing Course Syllabus	❺	❹	❸	❷	❶
	1.1.2	Planning Review Schedule	❺	❹	❸	❷	❶
	1.1.3	Designing Students' Learning Worksheets	❺	❹	❸	❷	❶

	1.1.5	Gathering Pictures	❺	❹	❸	❷	❶
	1.1.6	Gathering Audio and Video Material	❺	❹	❸	❷	❶
	1.1.7	Studying the Articles To be Taught	❺	❹	❸	❷	❶
	1.1.8	Surveying Educational CD Titles	❺	❹	❸	❷	❶
	1.1.9	Browsing Related Web Sites	❺	❹	❸	❷	❶
	1.1.10	Looking Up New Characters and Phrases	❺	❹	❸	❷	❶
	1.1.11	Preparing Handouts	❺	❹	❸	❷	❶
	1.1.12	Making Lesson Plans	❺	❹	❸	❷	❶

Table 2: A Portion of Round 3 Questionnaire

The 90 items were presented to the participants in the third-round questionnaire, asking them to assign a rating of 1.0 (least important) to 5.0 (most important) to each. By this we intended to find out how important teachers thought of each task in terms of needing ICT skills to help them accomplish the task. The 18 participants' ratings for each item were averaged to derive the *priority factor* for it.

The items were ranked from the most important to the least important according to their priority factors. The ratings and the rankings were then provided in the fourth round questionnaire to solicit participants' further comments. In particular, we asked them to explain in more detail about several task items and tell us how they thought ICT might assist in those tasks. For example, one of the eight questions asked was: "Task item 1.2.1.6.7—'teaching of rhetorics' and task item 1.2.1.6.8—'teaching of Chinese grammar' received an average ratings of 3.56 and 3.50, ranking 48 and 50 respectively. What are the specifics of these two task items? What do you think that ICT can help in improving teaching and learning in these two respects?"

Among the 90 tasks items that were presented for rating, Table 3 shows the 10 top-ranking items. It is interesting in noting that only three items, the shaded rows in Table 3, are directly related to teaching. In fact, of the 55 directly teaching-related items, only 25 items (45%) ranked in the top half, compared with 20 of 45 (57%) administrative task items. In other words, the respondents seemed to have regarded ICT skills more relevant to administrative and communicative tasks than to teaching tasks. This finding is not surprising, considering that previous studies, such as the ones done by McCannon & Crews (2000) and Clark (2000), have repeatedly shown that more teachers used the computer for administrative tasks than to enhance classroom instruction. However, given that ICT integration in subject teaching was rarely practiced in Taiwan's secondary schools, much less in Chinese language arts instruction, our participants' awareness of the potential benefits of using ICT within the curriculum might have thus been greatly confined. After all, it is much easier to relate administrative and communicative tasks to ICT skills than to relate teaching tasks to ICT skills. For example, a respondent could have readily connected "computing and analyzing students' grades" (ranked No.1 in (Tab. 3)) with common spreadsheet tools or "publishing students directory" (ranked No.6) with word processing tools. In contrast, it would be much harder for them to see what the use of ICT might have to do with "teaching of Chinese grammar." Realizing this general fact, the teacher training providers in Taiwan should try to offer more training programs oriented toward integrating ICT into instruction so that our teachers can become more educated in the theories and practices of ICT integration. This, in turn, calls for more training material designed to serve that purpose.

Rank	Task Item	Average Rating
1	Preparing Exam Papers	4.94
1	Computing and Analyzing Students' Grades	4.94
1	Preparing Grade Reports	4.94
1	Developing and Maintaining Student Web Site	4.94
1	Developing and Maintaining Chinese language arts Teachers' Web Site	4.94
6	Managing Test Bank	4.89
6	Publishing Student Directory	4.89
8	Preparing Presentation for the Meetings	4.83
9	Designing Students' Learning Worksheets	4.67
10	Preparing Meeting Agendas and Minutes	4.61

Table 3: The 10 Top-Ranking Task Items

While we were pursuing the details of professional tasks involved in Chinese language arts instruction throughout the survey, questionnaires 2, 3 and 4 also contained a second section in which questions were posed to elicit responses concerning how ICT could help in some particular aspects of Chinese language arts instruction. The six questions in the second-round questionnaire asked about how the participants thought of the computer as a teaching aid, especially in contrast to the traditional teaching aids they had used before. The third round questionnaire contained five questions asking the participants to assess the potential benefits and possible obstacles of using the Internet in Chinese language arts instruction. We put special emphasis on the Internet because we considered it the most promising technology in revolutionizing the way of teaching and learning. With the fourth round questionnaire, its Section 2 contained two questions that were related to the use of ICT in keeping students' records and preparing grade reports. All these questions succeeded in generating from our respondents many useful ideas that can be used to enrich our training material, as will be mentioned again in the next section.

Mapping Task Items to Training Units

Since our ultimate goal is to design training material for Chinese language arts teachers based on the task items derived from the survey result, we need to map these 90 task items to a suitable number of training units. We

BEST COPY AVAILABLE

began by making an assignment of software/hardware tools to each task item. That is, we tried to identify the software/hardware tools that teachers would need to learn to perform that task more efficiently or innovatively. The assignment was based on the task description that our respondents gave in their responses to the questionnaires, as well as what they suggested that ICT might help with the tasks. (Tab. 4) shows the software/hardware assignment for the 12 task items that appeared in (Tab. 2). Taking Item 1.1.6 (i.e., "Gathering Pictures") as an example, we assigned three application tools (i.e., web browser, picture viewer, and image editor) and two hardware tools (i.e., scanner and digital camera) to it. Some of the task items that the teachers found not really necessary for involving the use of ICT, and which we also agreed, were omitted from this assignment. For example, Items 1.1.7 and 1.1.10 (ranking 74 and 83 among the 90 items) were dropped during this assignment process.

Task Item	Software	Hardware
1.1.1 Preparing Course Syllabus	Word Processor (e.g., MS Word)	-
1.1.2 Planning Review Schedule	Word Processor	-
1.1.3 Designing Students' Learning Worksheets	Word Processor	-
1.1.4 Gathering Textual Material	Word Processor Web Browser (e.g., Internet Explorer) Chinese OCR Software	Scanner
1.1.5 Gathering Pictures	Web Browser Picture Viewer (e.g., ACDSee) Image Editor (e.g., PhotoImpact)	Scanner Digital Camera
1.1.6 Gathering Audio and Video Material	Web Browser Multimedia Software (e.g, Windows Media Player) Digital Audio Editor (e.g., GoldWave) Video Editor	Camcorders CD-ROM Drive DVD-ROM Drive
1.1.7 Studying the Articles To be Taught	-	-
1.1.8 Surveying Educational CD Titles	Web Browser	-
1.1.9 Browsing Educational Web Sites	Web Browser	-
1.1.10 Looking Up New Characters and Phrases	-	-
1.1.11 Preparing Handouts	Word Processor	
1.1.12 Making Lesson Plans	Word Processor	

Table 4: Software and Hardware Tools for the 12 Items in Table 2

It is apparent from what is shown in Table 4 that more than one task item would end up being assigned the same or similar set of software/hardware tools. For example, popular application tools such as word processor, presentation software and web browser would be used in many of the tasks. In such cases, we grouped the task items that were similar in nature into a single unit. For example, Items 1.1.1, 1.1.2, and 1.1.12, were merged into one. On the contrary, some task items that were found to be too coarse-grained or that involved the use of too many software/hardware tools were split into two or more items. For example, developing student web site was further divided into eight separate units because of the complexity of ICT skills involved; items 1.1.5 and 1.1.6 also required more than one training unit. The guidelines we used were that each unit should contain the right amount of material for a three-hour training session and that each unit should enable the trainees to produce something practical that they could readily use for instructional or other purposes after attending the training session.

The restructuring yielded a list of 57 training units, among which 39 units were related to integration of ICT into Chinese language arts instruction, and 18 units concerned teachers' administrative and communicative tasks. Integration-related units included such units as "Use of Presentation Tool for Theme-Based Writing Instruction" and "Use of Internet Publishing in Writing Instruction." We then added 10 "Getting Started" units to it to cover the basic computer concepts and skills that teachers need to learn before they proceed to latter units. This resulted in a total of 67 units at the end.

As it is not possible to develop training material for 67 units all at once, we selected six of them for implementation in the tryout phase. With this trial implementation, we had intended to demonstrate what we meant by "subject-specific" training material. Other than covering knowledge and operational skills of certain software/hardware tools that we specified for each unit, each unit had contained learning activities and examples/exercises that were closely connected to Chinese language arts instruction. We borrowed many useful ideas from the participants' responses in the survey while we were creating contents for these units. Furthermore, we engaged five of the 18 participants in the design process to help provide subject-specific contents as well as suggest suitable writing style. (Tab. 5) shows one of the learning activities included in a unit entitled "Locating Instructional Material Using Directories and Search Engines." In this activity learners were guided through the steps of searching for resources about Su Shi, a famous poet of Sung Dynasty in ancient China.

Activity 4: Using a directory to locate resources about Su Shi
Go to: http://www.yam.com and click through the following links to narrow your focus:
Step 1: Select "Arts & Humanities" from the directory's broad categories.
Step 2: Select the "Literature" subdirectory.
Step 3: Select the "Chinese Literature" subdirectory.
Step 4: Select the "Classical Chinese Literature" subdirectory.
Step 5: Select the "Poetry & Lyric Songs" subdirectory.
Step 6: Read the short description about each web site and follow the links to desired web sites.

Table 5: A Learning Activity in a Training Unit

Conclusions

In this research we attempted to define the scope of Chinese language arts teachers' ICT needs based on an analysis of the professional tasks they performed routinely. We came up with a list of 90 task items, which were finally mapped to 67 training units. Training material for six of them have been developed in the tryout phase to demonstrate the concept of implementing "subject specific" contents. We have arranged a partnership with a junior high school in Taipei County to field test these six units in a training course offered to 17 Chinese teachers at that school. Feedback collected from this training course will be used to improve our design of other training units in the future.

Beyond the Current E-Learning paradigm: Applications of Role Play Simulations (RPS) - case studies

Contact Author: Roni Linser roni@ausis.com.au
Albert Ip albert@dls.au.com

Current E-learning models have been criticised by constructivists for providing content without a learning social context and have argued that such learning contexts need to be designed into E-learning programs. This paper takes issue with this approach arguing that it unnecessarily imports into E-learning assumptions and strategies from the traditional classroom/lecturing environments.

The paper explores some general pedagogical principles and outlines a pedagogy that takes the next step in redefining the social space of learning enabling educators to leverage the capabilities of the new communicative media as well as enhance and expand current models of E-learning beyond traditional models. This pedagogy is then demonstrated in a number case studies where learning is achieved using Role Play Simulations (RPS). It will be argued that RPS enable diverse learning objectives, from diverse subject domains, and thus constitute a useful pedagogical model of good E-learning.

The Current E-learning Approach and its Discontents

There is increasing concern among researchers, teachers and adminstrators that the new technologies for E-learning are used to deliver content without providing appropriate context for learning. As Kathleen Gilroy from MIT says "The emphasis of most E-learning programs to date has been on the accumulation, organization, and delivery of content." (Gilroy, 2001).

Similarly Professor Stills from Staffordshire University reminds and warns us not to assume that the delivery of content by the computer in virtual learning environments is sufficient – a computer cannot replace a teacher. (Stills 2001). And Tony Featherstone bemoans what he calls the 'transmissive' approach which focuses on transmitting content rather than providing a context for learning (Featherstone, 2001).

The call from these and similar social constructivists is that the social space of learning needs to be addressed in the design of virtual learning environments. Gilroy suggests that it is "the knitting together of content, pedagogy, and community into a unique learning experience, which is what people are buying when they step on to the MIT campus." And thus "E-learning should be first and foremost about creating a social space that must be managed for the teaching and learning needs of the particular group of people inhabiting that space." (Gilroy, 2001). For Professor Stills, virtual learning environments must be separable from content and Featherstone suggests a shift in focus from using the technology as a delivery medium to its use as a pedagogical tool in a constructivist mode.

The crux of these arguments is that we need to somehow integrate the social context of learning with the content delivery capability of E-learning programs in the way that the traditional MIT merges content pedagogy and social context. In effect this approach proposes to design E-learning programs that reproduce the traditional learning environment on-line.

To understand the weakness of this approach we need to more closely analyse and understand the relationship between content, pedagogy and social context or community. On the one hand, and in the general sense, every educational context presupposes three pedagogical objectives with regard to content: the acquisition by learners of (a) knowledge (b) understanding and (c) skills, particular to their fields. Though sometimes the emphasis may be for learners to acquire certain skills, it is more often entwined with particular kinds of knowledge and understanding. At least in the social and human sciences we more often hope that learners also gain an understanding and expand their knowledge. The content of that knowledge, understanding and skills of course depends on the particular discipline and course content.

On the other we have to select the best means to deliver that content so that these pedagogical goals can be achieved, including being pro-active in situating both means and content within the social context of learning. As Gilroy suggests above and as all constructivist models emphasise, apart from the way content is presented on-line we need to create a social context for learning. Indeed, one of the main strengths of the constuctivist approach to E-learning is this demand - the collaborative learner centered approach is another. But is it advisable to re-create the traditional social context of learning on-line?

On the surface, given our experience of traditional modes of learning and the constructivist critique of E-learning, it seems plausible to create an on-line community that will serve the same function in E-learning programs as the traditional social contexts for learning do in traditional modes of learning.

However, there are at least two powerful reasons why creating traditional learning contexts on line is counterproductive. Firstly because traditional learning contexts are based on assumptions regarding communication and social space, authorship and authority, that are too narrow with regard to, or are not reconcilable with, on-line environments. And secondly, there are still technological constraints that actually exclude putting on-line precisely what is the most useful ingredient of the traditional environment - the dynamic intimacy of face to face interaction.

In principle, as George Mead has argued - communication is the organizing principle of a community[1]. Thus to understand the learning environment and the community of learners within it, we must attend to the underlying communicative organization of that environment (Linser & Naidu, 1999).

The social space of learning in traditional learning environments[2] is largely based on face to face communication supplemented and infused by the written medium. By contrast, on-line learning environments, are mostly written and iconographic supplemented by face to face communication and/or virtual synchronous interactions. The types of structural codes and constraints of traditional face to face environments on communicative interaction that lead to both appropriate[3] selection and acquisition of knowledge, understanding and skills by learners, are so intricate and sublime that it is, at least presently, impossible to reproduce them on-line. It is like delivering a not so funny joke in such a way that it is hilarious as opposed to reading the joke.

We are dealing here with a wide gamut of linguistic and para-linguistic codes that sustain the traditional learning environment and are specific to a community of learners. These codes and constraints, relative to specific cultural and locational contexts, define the authority, validity, appropriateness and the allowed and/or required level of learners participation among other things. In short they define who can say what to whom, in what channel, how it is to be interpreted and the degree of reliability.

The many subtleties of face to face interaction that constitute the background to the traditional learning environment are at the very least, at present, very costly to achieve on-line, if not impossible. But that does not mean that we should abandon the constructivist approach. Rather the task is to re-define what constitutes the learning social context. If indeed we can create a social space on-line, why create the traditional learning environment when we can create the social space of the content itself ? And if the tools which the new technologies of communication provide can create the course-content itself as an interacting social environment in which the learner is a participant then there seems no need to create an additional social context. In other words, our suggestion is that rather than reproduce the learning space of traditional paradigm, use a simulated social space in hyper reality to bring to life the course-content itself. And this we suggest can be achieved for every course-content that has as its focus human social relations and organization because the principle underlying these is communication.

---

[1] This is not the place to go into a detailed discussion on theories of communication and power with regard to educational contexts, and so the presentation here is only sketchy and at a very general level. Suffice to say that what is presented here relies on sociological, socio-linguistic and medium theories of communication.

[2] i.e. the traditional space of lecture halls, classrooms, hallways, libraries, administration and lecturer's offices, cafeterias, student union, sports grounds, clubs, societies etc…

[3] i.e pedagogically intended

RPS pedagogical strategy

The question is how to create course-content as an interacting social environment. To do this we are relying on a pedagogy that infuses dynamic goal-based learning, role-play and web-based communication and collaboration into a powerful pedagogical tool based on learner centred and collaborative principles. Elsewhere we have outlined the pedagogical structure of RPS so the exposition here will be brief (Linser, Naidu, & Ip, 1999*)*. Particular examples of how this works in practice will be provided in the next section.

The general idea is to simulate on line aspects of the social context relevant to the course-content by letting learners act out the various roles that constitute the reality addressed or problematized by the discipline.

Dynamic goal-based learning is a strategy that leverages the experience and motivation of participants trying to reach a goal, in the service of pedagogical objectives. The idea is that in attempting to achieve game goals, especially ones set by themselves, in a dynamic and reflexive environment, i.e. one which continuously emerges from the impact of their own actions; participants will be motivated to evaluate, learn, and exercise the necessary skills required to be successful in order to reach these goals and in the process acquire the knowledge and understanding needed.

Taking on a 'persona' in a **role-play** simulation involving multiple roles whose objectives may be in opposition or in alignment with the 'persona's' own objectives, creates such a dynamic and reflexive context for participants. Given that all roles must respond 'in character' to an initial scenario, and further, must respond to the actions of other roles, a reflexive and dynamic process emerges that continuously provides participants with the impact of their own actions on the context. Thus, they must acquire more information, reflect and then adjust their further actions in order to reach their objectives, or indeed perhaps even alter or abandon them and set new ones. The idea of 'play' cannot be over-emphasised and should be understood in its senses of playing a game, playing a role in a play, and in the sense of playing with possibilities (experimenting).

The communicative interaction of such a role-play simulation in the on-line environment of the **World Wide Web**, has the further advantage of providing a space that can be used in both synchronous and asynchronous modes. Moreover, the ability to create a 'persona' as opposed to the real identity of the student has many advantages - not the least of which is to provide a sense of security for the learner. Still more, this on-line environment provides a space where the resources needed for acquiring the necessary knowledge for playing the game, can be made available 'just in time' when they are needed. And this includes moderators who become a resource in the service of game objectives through which they fulfil pedagogical objectives. If moderators are also sensitive and committed, our RPS environment (supported by the Fablusi platform) creates a 'safe' and supportive space for participants to learn from their own experience.

The upshot of playing the game, of attempting to implement different strategies and seeing their outcomes, is that participants learn the subject's content, acquire skills and learn to understand what is involved in the process. And this is precisely the pedagogical utility of RPS [4].

The uniqueness of this pedagogical structure is that it separates the learning space, where participants learn from their experience, from the institutional and organizational environment which provide the resources for learning including moderators or educational facilitators. It does so without reproducing these institutional and organizational aspects of the learning environment e.g institutional hierarchies. The structure of RPS thus creates a flexible space for participants to fill with their own objectives, actions, and results that ultimately relate back to the pedagogical objectives of the course as set down by the institution.

4 Case Studies

So what does a 'social space of the content itself' look like? how does it provide a social space for learning? and is it helpful in reaching the pedagogical objectives of courses in which this is implemented? What follows is a brief description of a number of different applications of role play simulations using the pedagogy above.

---

[4] for more info on the pedagogical foundations of RPS see Linser & Naidu, 1999; 2000, for the role of Moderators see IP Jasinski and Linser, 2002 forthcoming.)

The most important aspect in RPS design is the decision on which roles and what kick-start scenario will best serve the particular pedagogical objectives of the course. The relations between the roles within the kick-start scenario and their differential membership in asynchronous 'forums' modelling institutions and organisations derived from the course content, provide the social space and context for learning. And it is to these which we now turn relative to the particular pedagogical objectives of the different courses.

2 Simulations of International Politics [5]

Over the past 11 years we have conducted RPS for a variety of political science courses at the University of Melbourne, including Middle East politics, World Politics, Theories of Power, Russian Politics, Australian Foreign Policy, and International Politics of the Asia-Pacific. In general the stated pedagogical objectives of all these courses included understanding the political processes and dilemmas faced by leaders in these regions and the theories and explanations that may be useful to understand these processes. All of these courses were originally lecture based with essays and tutorial participation as their mode of delivery. For all these courses students were given the choice between participation in the simulation involving working on roles as teams or individually doing another essay or exam. Significantly in all these courses the majority usually choose to do the simulation despite the fact that they were warned and knew from former students of the course that it involved more work than the other alternatives. (see Ip, A. & Linser R., 2001)

For the sake of brevity I will discuss the content of only two of these simulations. The Russian Politics course focused on the internal political dynamics between the central government of the Russian Federation and the governors of the Regions. Because of the small size of the class (45 students), we decided to focus the simulation on only 3 regions, the internal security forces, the army, the government, 2 opposition parties (to the right and left of the government) and the media (16 roles). The kick-start scenario then provided a short overview of the current situation in Russia with the President calling for reform of the State council – the organization that brought together the leaders of the regions. To this was added a fictional element that during a recent meeting of this council some governors severely criticised both the reform and the president and stormed out. Thus a conflict of interests between the central government and the regions was set in motion, requiring all the roles to take sides, to negotiate, threaten, cajole, back-stab and generally attempt to secure the aims of their respective roles (which they have researched and published on the web-site before being aware of the initial scenario.)

This was a fairly simple simulation focusing on just one set of issues - but the overall effect was the creation of a space of relations, modelled on the real world which the course content addressed as narrative in lectures. A social context was created and developed in the conjunction of research efforts and response to simulated events, that participants themselves set in motion. And this served as a context for learning the historical facts, the organizational relations and some of the possible processes that can occur within Russian Politics.

A more complex simulation involved two different courses in the same department, the Australian Foreign relations course (120 students) and Theories of Power course (45 students), both taking part in a joint simulation [6]. Each of these courses obviously had different contents, so we decided to create two types of roles. One type, like in the Russian Politics simulation, focused on Australian foreign policy issues from the perspective of the government, the opposition parties, the military, and Australia's neighbours in the region including US and European powers. The other type of roles which could only be taken by students in the Theories of Power course, were of theorists, commentators, and advisers. The initial scenario involved a fairly comprehensive overview of real events and process in the region and different fictional crisis in Australia's immediate region - clashes between the Indonesian army and local rebels in Aceh, West Papua and East Timor as well as reports of money laundering in some of the smaller pacific islands.

---

[5] <http://ausis.com.au/polsim>

[6] We have also had simulations that brought together different courses from different universities around the world.

The interesting aspect of this simulation was the cross fertilisations of issues. The 'theory' based roles had to publish explanations of the simulation events as they were occurring from the perspective of different theoretical positions, Weberian, Arendian, Faucauldian etc, and give advice to the more 'political' roles who then accepted or rejected these as basis for action, and used them as justification or condemnation of others relative to their political interests and priorities. Again we see how a social context for learning can be created from the contents of very different courses by creating specific kinds of roles to fit the course content. This in turn shifts the students focus on the contents of their course and from this perspective evaluate and use what other students produce in other courses for their own purposes.

Australian History: the First Fleet 1788 Simulation[7]

Professor Sandra Wills from the University of Wollongong has developed a database of the convicts who arrived on the First Fleet to Australia in 1788 and has added a role-play simulation as an active learning methodology for students to develop a better understanding of the lives of those involved in the early days of white Australian settlement.

In this simulation players adopt the roles of either convicts or officials of the colony in an attempt to solve the problem of theft. Unlike, the political science simulations above, participants do not research their roles but are given a description of their character, which is based on known historical fact found in the database. Depending on their role, each belongs to one of the following camps: Governor's Table, Officers' Mess, or Convict Camp which has two subsections.- female gossip and male gossip. Each character can communicate either privately with a particular character or post a general message for all to 'hear' in their camp. Other camps cannot see these conversations until the group collaboratively decide to share it with others. The scenario, also based on the historical record, revolves around the decreasing food supplies, the action of some to plant vegetable gardens, and others who steal the vegetables because there is nothing to protect the more law abiding community members, who are tired of seeing their gardens raided. How will order be maintained? How will thieves be brought to justice to deter others? Those are the problems that participants tried to solve.

Unlike the simulations discussed above, the pedagogical objective here is to bring to life the records of a database so that students better understand the historical conditions of early white settlement in Australia rather than current affairs and concerns. The social context for learning is developed out of the contents of the database and the interactions between roles within and across 'camps' constitute the collaborative arena for finding a solution. In the process students acquire, knowledge of the facts, an understanding the difficulties and skills for researching this database.

Staff Development and Sexual Harassment[8]

This simulation was developed as a tool for a staff development project at the Douglas Morley Institute of Technology in Adelaide. The pedagogical objective was to provide training in creating and using web-based role play simulations. We decided that the best way to achieve this objective was to actually play a simulation before the training began and then leverage the experience in workshops where participants then worked in teams creating their own simulations for particular courses which they deliver to students - one of these is the Fashion House simulation that was later actually used in a course about fashion design.

We decided that 'sexual harassment' would be a useful topic as participants in this kind of educational context would be familiar with this sort of content and participants would be able to explore this issue in the overall context of training in creating simulations. By not having to do much research in order to act appropriately 'in character', participants would be able to spend more time on thinking through the pedagogy and experiencing the capabilities of the software, as well as their limitations This enabled participants to reach the ultimate objective of being able to create and run such simulations.

---

[7] <http://www.dls.au.com/firstfleet>

[8] <http://www.roleplaysim.com/default2.asp?SimID=rpsim00000123M1B>

Unlike the simulations above the setting (an educational institute) and all roles (16) in this simulation were fictional and so each of the roles was given the position of the role (like head of the Institute, secretary, ceramics teacher, equal opportunity officer etc.) and an outline of the character of role (e.g. the Managing Head of the institute was characterised as authoritative and intellectual, open to rational argument, recognized as a good mate, hates details, gives subordinates lots of freedom and in return, expects them to resolve their own issues. Has an inner circle of trusted colleagues where you can let your hair down and tell it like it is…). The initial scenario, again totally fictional, was designed to bring out possible areas where sexual harassment may become an issue and thus the roles faced the task of collaborating through their 'persona' to identify and resolve these issues where possible.

To what extent are these RPS effective in reaching pedagogical goals?
In the social sciences, I suspect the degree to which any pedagogy actually achieves its objectives will always be contested grounds. Research on the effectiveness of RPS is still scant . What is there suggests that it is a transformative experience for most learners who by enlarge report gains in knowledge understanding and skills specific to their subject (Ip & Linser, 2001; Vincent & Shepherd, 1998). However, the novelty of the approach may be skewing the judgement on the relative effectiveness of this approach as perceived by learners. As a user and observer the impression is that not only does it reach the pedagogical objectives but does so above expectations.

Summary: Good E-learning and how to make it better using role play simulations.
The argument that E-learning programs need to not only deliver content but also a social context for learning is acceptable if the social context for learning is not simply imported on-line from traditional learning contexts. MIT may have a winning formula in its traditional context, but that is because the underlying structures of face to face communication anchor the relationship between the local institutional spaces of MIT to content and pedagogy. But we cannot, and should not attempt, to reproduce this on-line. A different social space already exists in on-line environments and to reproduce another context on-line seems unnecessary if not counterproductive. The social context of learning can be created from the content itself. If we can create social spaces on-line than in so far as disciplines connected with the social sciences are concerned, that content can be created as an interactive learning environments with unique, though simulated, social contexts for learning as our 4 case studies have shown.

Significant Features Of Asynchronous Learning: Summary of a Pilot Study[1]

J. R. Llanes
University of Texas Pan American

Abstract

The development of computer-mediated asynchronous platforms for the delivery of online coursework brings college professors new questions about the features these platforms offer and the degree to which each feature is significant to the achievement of students. Are all features designed in the same way across platforms? Are there some features which are more reliable, easier to operate and more attractive to students who use them? Which of the features can be connected with objective measures of achievement? Is the type of use given to the feature by an instructor a significant element of the feature? This paper relates a pilot study of three courses offered online using three different platforms and in three different campuses in order to explore the range of features in use and their link to student satisfaction and achievement. It also contrasts student outcomes with three onsite courses offered by the same professors. The long-term purpose of this study is to learn about hypothetically significant features that can then be improved.

Review of the Literature

For the sake of brevity in these Conference Preceedings there will not be a review of the literature in asynchronous learning or the meassurement of significance as an element of a learning model. In order to obtain features we tapped a "benchmarking" study conducted by a private research organization, the Institute for Higher Education Policy (IHEP), located in Washington, D.C. The sponsors of the study, Blackboard Inc. the producer of one web platform and the National Education Associationa political organization of teachers, to which I belong, clearly had some interest in the outcome. The method IHEP used, however, closely resembles the standard methodology for securing "benchmarks" in the private sector and in educational quality systems in which State standards are often based. The participants in the study, which were also visited and polled on the crucial elements of the process; were quite diverse institutions of higher education and some were representative of our type of institution. Thus, armed with little but useful knowledge, we began to study. In fuller-length papers the literature on measuring significance and on asynchronous models can be discussed

The Pilot Study

The courses and grading policy

Three professors, who teach graduate courses online and also have the option to teach these courses onsite, offer the same course in the two versions in the same term. The courses are offered to graduate students of educational administration.

Each student is graded in three areas:

1) Student Participation refers to how often a student speaks in class (on the onsite courses) or posts messages on the Bulletin Board or the listserv (on the online courses). There's also a determination made by the graduate assistant on whether or not the comment or question is on-target. There are 15 weeks on each course but the maximum grade is 40, so there is a top limit or "ceiling" to classroom participation.
2) Group Project refers to a cooperative activity in which teams selected by the professor collaborate to obtain a maximum grade of 30. The grade is given for the entire team.
3) A Final Exam is administered containing 15 questions, which can receive a maximum grade of 30.

Measures

The courses are then compared with each other on the following factors:

1) The grades received by students
2) The participation grade
3) The group project grade
4) The final exam.

There are two surveys given to each student, one during the first week and another during the 13th week. In addition, university-prepared course evaluations were given to both groups as mandated by university policy. These results are compared.

Analysis of Data

1) The drop-ad activity for onsite courses was higher than for online Students enroll in the courses as required by their degree plan, without knowing that one of the courses would be held online. At the first meeting, the professor announces the study to those selected to be in the online course. Students could drop the course if they did not wish to take it online and they were then assigned to the onsite course. Of the 43 students who were given this option by the three professors, 3 decided to change the course at that point leaving 40 students and there were no subsequent drops. In the onsite courses, 45 were originally enrolled, adding the three who opted out of the online course, raised this total to 48, however 6 dropped or withdrew during the course leaving 42. The students on the onsite course were not told about the study or the availability of the online course. The drop-add activity for each course was higher for the onsite course. Table 1 shows student retention.

Table 1 Student Retention

Type of Course	First-day Enrollment	After 4 weeks	After 8 weeks	Completed
Online	43 (100%)	40 (93%)	40 (93%)	40 (93%)
OnSite	48 (100%)	45 (90%)	42 (87%)	42 (87%)

This is not typical, dropping online courses is much more prevalent than in onsite courses. This atypical behavior maybe due to the fact that these online students were aware of the research being conducted and were eager to cooperate with it.

2) Females did generally better in final grade across the three course pairs. See Table 2.

Table 2 Comparison of Females versus Males on Final Grade

Gender	C1online	C1oniste	C2online	C2onsite	C3online	C3onsite	Average
Females	80.2	78.7	74.7	86.1	78.3	86.1	80.7
Males	76.4	71.9	71.6	84.3	82.3	88.3	79.1
Average	78.9	72.9	72.5	85.7	80.5	87.1	79.9

3) This was not true however in the variable of Participation. In this variable males, both onsite and online received a better Participation grade than females. The reason for the higher overall grade by females seems to come from a higher grade in the Final Exam. Since Group Projects were carried out, in all but two teams, by mixed-gender teams, it was not possible to compare gender outcomes in this variable. Table 3 contains the data on the Participation comparison.

Table 3 Comparison of Females versus Males on Course Participation

Gender	C1online	C1oniste	C2online	C2onsite	C3online	C3onsite	Average
Females	25.1	15.2	14.3	33.1	21.4	30.9	23.3
Males	27.8	16.2	18.1	31.8	25.9	37.9	26.3
Average	26.6	17.1	16.8	32.5	23.0	34.6	24.8

4) On the Participation variable we found that online Course 1 had a higher student participation grade than the onsite version. In the other two pairs, the onsite classroom participation is considerably higher. The online participation was obtained by counting and evaluating the postings made by students to their discussion group boards and also including e-mails sent to the listserv. However, the onsite course rating was an interpretation made in-class by student assistants. Since we did not conduct inter-rater reliability research prior to conducting this preliminary study, and three different graduate students were used to rate onsite student participation, we cannot be certain that this difference is not related to different raters' perspectives.

5) A review of the online Bulletin Boards was conducted to determine what kind of behavior on the part of the professor contributed to increasing or decreasing participation on the part of students. Like classroom participation, a professor can have an inhibiting effect by either ridiculing, excessively challenging or refusing to accept as valid, comments made by students. It is also the case that a professor can inhibit discussion on a question when she/he provides a quick answer to a question rather than remaining silent or asking others to voice their opinions regarding the question. The same appears to be true in Bulletin Board discussion. In Course 3 online, which experienced the lowest number of postings on the part of students (393), the professor answered nearly all postings containing questions before any other student had a chance to comment. Only when the professor was "disconnected" from the Bulletin Board, either because of travel or other activity, did students take it upon themselves to provide responses or opinions regarding another student's postings. Conversely, in online Course 1 which experienced the highest number of postings (1,097), student postings were allowed to remain unanswered for at least 48 hours and after the hiatus when the professor intervened, he often responded to questions with other questions which elevated the number of postings per issue raised.

6) This observation led to the development of a formula to estimate student responses to professor's interventions which fits the data from each of the three online courses as follows:

a) If professor waits at least 48 hours, then 40-50% of the students post responses or comments on others' comments;
b) And if professor asks questions about a student's posting (whether a question or a statement) then 70-90% of the students provide responses;
c) If a professor provides responses to each question and/or comment without waiting 48 hours, then 0-20% additional student postings can be expected.

This formula suggests that the professor's use of the Bulletin Board for classroom discussion is similar to professor's onsite interventions on student discussions in its effect on student participation. Given the higher correlation of Participation to Final Grade in Course 1, this feature and its use appears to be significant to overall student achievement. (See Table 11)

7) We expected that online courses would not be as effective as onsite courses on the variable of Group Projects. We hypothesized that, since the onsite classes had facilitated familiarity among students who met with each other every week; this would pave the way for a more effective teaming in the Group Project. This was true in Course 1 where onsite students averaged 28.8 on their group projects while online students achieved an average of 26.7. But the other two courses reflected the opposite of the expectation. See Table 4.

Table 4 Comparison of student grades on Group Projects Online versus Onsite Courses

	C1online	**C1oniste**	**C2online**	**C2onsite**	**C3online**	**C3onsite**	**Average**
Average	26.5	28.8	28.5	26.9	28.8	25.6	27.5

8) All three professors coordinated the preparation of a final exam so that it contained the same questions and was graded by one person, increasing the reliability of the score. Course 1 gave the test onsite to both online and onsite students in one Saturday. Courses 2 and 3 online gave the test using an external server owned by a commercial provider. The onsite versions of Courses 2 and 3 gave their exams onsite the same day the online exam was available to minimize "bleeding" of information from one group to another about the contents of the test. We found that students scored very close to each other when compared within course pairs and across course pairs. See Table 5.

Table 5 Comparison of student grade on Final Exam Online versus Onsite Courses

	C1online	**C1oniste**	**C2online**	**C2onsite**	**C3online**	**C3onsite**	**Average**
Average	25.6	26.9	27.8	26.1	27.40	26.7	26.7

Correlations

We correlated the final grade with the three scored variables, Participation, Group Project and Final Exam. These correlations gave us additional insight on how students construct knowledge using different modalities of delivery.

9) Students Participation scores correlated the highest overall with the Final Grade. In online Course 1, students Participation score correlated 0.944 (<.001) with their Final Grade. On Course 2 online, students Participation score correlated 0.870 (<.002) with their Final Grade. On Course 3 online, students Participation score correlated 0.682 (<.005) with their Final Grade.

10) When Participation scores are compared across online courses, we find that in Course 1 students online contributed 1,097 postings, a much higher number than in Course 2 where students contributed 498 and on Course 3 where students contributed 393. This also coincides with the higher participation score of students in Course 1 online, but it is

not even higher as it is limited by the ceiling placed on the grade the students can receive for this activity

11) The correlation between Participation and the Final Exam in online Course 1 is strong (.654<.001) while the Correlation between Participation and Final Exam in Course 2 online is a negative one (-0.192<.005) and in Course 3 online is very weak (0.063<.001).

12) The correlation between Group Project score and Final Grade were weak or non-existent. We think that the Group Project, intended to practice students in the art of collaborating toward a final product and is not a content objective per-se, therefore contributed less toward the achievement of a higher grade on a content-based exam. Also, since a) groups were organized on the basis of the distance between students' home addresses and not homogenously by previous performance, and b) the group received one grade for all participants; these grouping and grading factors conspired to produce a lower correlation between this factor and the final grade students received. In order to further sustain these hypotheses we ran a correlation between Group Project grade and Final Exam and found weak or no correlations between the two. See Table 6.

Table 6 Correlations Between Students Final Grade and Study Variables

	Final Grade and Participation	**Final Grade and Group Project**	**Final Grade and Final Exam**	**Participation and Exam**	**Group Project and Exam**
C1online	0.944<.001	0.492 <.002	0.774<.005	0.654 <.001	-0.456<.005
C1onsite	0.880<.001	-0.018<.002	0.378<.001	0.012<.001	-0.012<.005
C2online	0.870<.002	0.225<.002	0.250<001	-0.192<.005	0.013<.002
C2onsite	0.897<.001	0.669<.002	0.258<.001	-0.014<.005	0.023<.002
C3online	0.682<.001	0.549<.001	0.447<.001	0.063<.001	0.167<.005
C3onsite	0.755<.001	0.353<.001	0.128<.005	-0.382<.002	0.239<.005

Student Satisfaction

13) The level of overall satisfaction, as measured by the student surveys, were fairly high with the online courses (68% of the comments being positive) but slightly lower than the level of satisfaction with the onsite course (71% of the comments being positive). The following Table 7 details the overall satisfaction scores.

Table 7 Comparison of Onsite and Online Courses on Overall Satisfaction

	Course 1	**Course 2**	**Course 3**	**Average**
Online	78%	72%	56%	68%
Onsite	82%	74%	57%	71%

14) The differences between the pre and post surveys are greater for the online course than for he onsite course on the variable of student apprehension. In the pre-course survey 42% of the students expressed High or Very High "stress" stemming from how

they would do in this course, compared to 18% of the students in the onsite course. However in the post-survey the online students apprehension with future course online fell to (15%) more in line with the level of apprehension in the onsite course.

15) The three university-prepared course evaluations cannot be fully compared because each are prepared with different criteria and item construction making them essentially non-equivalent measures. However some of the items are sufficiently similar to allow for some comparison. The following are some of the variables of interest to this study. See Table 8.

Table 8 Comparison of results of university-prepared course evaluation on comparable values across campuses

	Overall rating as Instructor	**Instructor outside availability**	**Courtesy to students**	**Clarity of Course Objectives**	**Encouragement of critical thinking**
C1 onsite	100%	100%	100%	100%	100%
C1 online	90%	90%	100%	80%	100%
C2 onsite	85%	90%	100%	100%	90%
C2 online	80%	70%	80%	70%	90%
C3 onsite	78%	80%	80%	80%	85%
C3 online	76%	70%	60%	70%	85%

Conclusions

At the beginning of this study we had four research questions which we will repeat here and summarize findings in response to these.

Are all features designed in the same way across platforms?

Because different people designed each platform and each is a descendant of platforms designed for differing purposes, the platforms' features are therefore measurably different in design. We lack sufficient data required to make a definitive statement on which design provides the most significant input to student achievement. One might be able to discern differences with large samples over time but not from this small sample. We have become familiar with three platforms, which are essentially effective in enabling the presentation of material. Some are easier to operate by professors unfamiliar with the technology, while others require at least rudimentary knowledge of HTML. Since most professors end up doing their own course design after an all too brief period of institutional support, each platform could use a simpler method for designing and incorporating course materials.

Are there some features which are more reliable, easier to operate and more attractive to students who use them?

Given the levels of actualization reported earlier it appears as if the features of all three platforms have a long way to go before they are able to give students a trouble-free operation. When compared with the use of listserv to engage in dialog, Bulletin Boards are considered superior by students overall. But when compared with the internal e-mail facility of all platforms tested, external listservs were judged by students to be more effective. One course with a CD-ROM of lectures provided a higher level of satisfaction with professor's explanations than the other two. Still, the CD-ROM feature could not be linked with online material in any platform, so the student had to logout of the course and start the CD-ROM before he or she could use the material.

Which of the features can be connected with objective measures of achievement?
We were able to correlate the use of Bulletin Board with both Final Grade and performance in Final Exam. Students rated online Course 1 as Very Effective in conveying information through web pages and Courses 2 as Effective and 3 as Moderately Ineffective. The features are hypothetically linked to achievement but the use given to them by individual professors may be even more important than the construction of the feature itself. In summary, there are no other features than correlate to student achievement.

Is the type of use given to the feature by an instructor a significant element of the feature?
This seems to be the most important area of findings. The simple answer is, yes.

1) Course 1 uses a format for presenting information, which is different than the other two courses. The author calls it Learning Text and it relies on learning theories on how to organize information for adult learning. Students find this format Very Effective when compared with the other two courses that use the more usual lecture notes format independent of any named theoretical construct.
2) As discussed earlier, the level and style of use of e-mail and Bulletin Boards by different professors reveal that the professor's communication style has an impact upon the amount and breadth of the student's communications online. As is the case in classroom instruction, online instructors must allow time for students to respond to the comments or questions asked by other students.
3) Higher levels of Bulletin Board use leads to higher correlations between this variable and final grades as well as higher scores on final exams. We also noted that students who are less participatory onsite are more participatory online.

Abstract: Multi-media classroom technology provides a unique opportunity to augment the classroom experience. Coordinating instructional streams with student feedback and assessment will enable instructors to know when and if their intended message was communicated to their students. A system where both instructional and presentational aspects of a lecture can be evaluated promptly will permit instructors and students to react quickly when there is a gap between intent and understanding, improving instruction. Presented here is a multi-media, e-classroom framework where information can be gathered to measure student, faculty and organizational achievement and to assist in improvement. Specifically, this paper focuses on using this e-classroom framework to improve instruction.

Introduction

Many different factors influence whether a student has successfully attained learning objectives. Student performance is rarely homogeneous, resulting in the familiar bell-shaped distribution. Causes for poor student performance are hard to pinpoint. Poor student performance is, in general, due to many factors, which may include: study habits, including test preparation; prerequisite material understanding; attitude toward class, for instance, individual interest in subject matter or attentiveness to class progress; attitude toward instructor; compatibility between student learning style and instructor presentation style; and attitude toward learning. These factors significantly impact how well students understand the core concepts of a course and how many of the learning outcomes they will achieve.

A strategy needs to be defined and tools implemented to provide the instructor with prompt feedback and assessment. According to Reid, "Firstly, it is necessary to develop policy frameworks, quality processes, and online tools to provide comprehensive, timely, and appropriate information that can be acted upon in order to improve the quality of learning. Secondly, such frameworks, processes, and tools should be applied in flexible ways that reflect the nature of the learning environments that they are aiming to improve." (Reid 2001) This framework must demonstrate that the intended content has been delivered to the student and that the student has received it. Further, it must facilitate improved instructor effectiveness. The resulting impact, as seen in Curve 2 (Fig. 1), on student learning should be "A Significant Difference" (Russell 1999).

Educational assessment has multiple, distinct uses in instructional improvement including: school and student accountability for academic achievement, feedback for teachers to revise teaching and administrators to allocate resources, and stimulation for students to receive deeper understanding (Baker 1999).

In most cases, the main criterion for assessing student performance is the degree of subject matter understanding. Student performance is evaluated at irregular intervals, through graded homework, quizzes, tests, projects, and final exams. Too often, students who were confused during lectures would not find out how far behind they were until it was too late to catch up. It is during the classroom contact time that the instructor can exert the greatest impact on student learning. In fact, a study from the University of Tennessee found that teacher effectiveness was the dominating factor affecting student academic gain (Sanders 1997). Thus, it is important to assess learning in the classroom and let instructors take timely measures and make any necessary remedial changes.

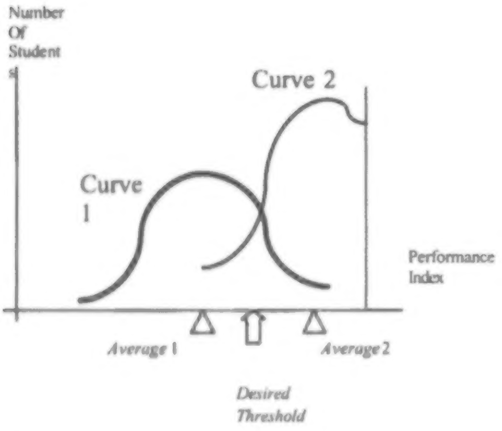

Figure 1. A Significant Difference

In terms of teaching evaluation, especially at the collegiate level, the burden of teacher and course evaluation falls upon the student using either in-class or Web-based survey forms. These evaluations are typically done only once, if at all. Since the survey is normally completed toward the end of the academic term, it does not impact students in the current class, though it may be helpful to future students in the same course with the same instructor. Also, since students may not take the survey seriously, the validity of the student response is questionable.

The important thing to note regarding the usual practices is that there is no correlation between student learning assessment and instructor teaching evaluation. Without timely feedback connecting student learning to instructor evaluation, neither the instructor nor the students have the power to affect change or to correct problems. Frequent feedback to the students advances student learning. According to Brien and Eastmond Cognitive Science and Instruction, "During instructional activities, the competencies taught must be reinforced each time they are adequately used by the learner." (Brien 1994) Further, Brien and Eastmond describe the "ideal" situation as one where the leaner knows the final goal as well as the sub-goals that support the final goal. Therefore, it is important that learning outcomes be explicit and feedback frequent.

Not only is frequent feedback to the student important for effective learning, but frequent feedback is also important to the instructor for effective teaching. As Reid notes, "...it is vital that students can provide feedback wherever they are receiving instruction, in a fashion that is seamless with their learning environment." (Reid 2001) Ovando adds, "...researchers are conceiving of teacher evaluation as a mechanism for improving teaching and learning." (Ovando 2001) Further, "...teacher evaluations 'must analyze teaching on the basis of what students are learning as well as effectively integrate the teacher evaluation and staff development processes with school improvement...'" (Ovando 2001)

With the recent advent of powerful computer technology for delivering media-rich content in classroom settings, many new possibilities are now available for augmenting classroom instruction and learning. Much of the current research using technology in the classroom focuses on innovative ways to use finite classroom resources or to overcome other logistical difficulties. Examples include video learning (Anderson 2001), where courses are video taped as an alternative way to deliver course content; on-line classes, where courses are taught via intranet or Internet sites with bulletin-board and email interaction (such as WebCT (Goldberg 1997)); distance learning and other Web-Based Instruction techniques. Web-Based Instruction is defined both as a delivery medium (Khan 1997) and as a content creation tool (Relan 1997). Unfortunately, in its current state Web-Based Instruction emphasizes content creation (information) and ease of use rather than pedagogy and instruction.

Although many new methods are available, the different formats of material being delivered during lectures may overwhelm students, hindering learning, causing student disengagement in the classroom. A fully engaging classroom technology should leverage, capture, share, and allow others to participate in the experiences (Duffy 1996). Duffy states, "It does not make good economic sense to allow knowledge to evaporate." (Duffy 1996). It is important to "...demonstrate how captured classroom lectures can serve as one part of a rich and dynamic educational repository." (da Graca Pimentel 2001).

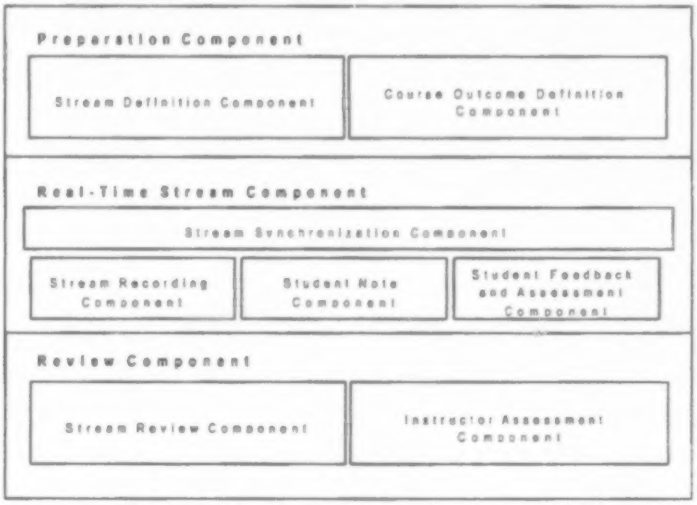
BEST COPY AVAILABLE

Research that focuses on getting more out of the classroom experience indicates that student needs and viewpoints have to be taken into consideration when course material is given in technology-based classrooms. (Hannafin 1996) As such, it is important for the instructor to know if and when the students are engaged so that proactive adjustments can be made. In summary, a system is needed for instructors to demonstrate they have provided the content and a feedback system for students to demonstrate that they have received it.

Approach: CaSA System Design

Networked computers or computing/PDA-based terminals are becoming widely available, so they should be used in classrooms to enhance learning through active interaction between students, the instructor and the material. To make use of this new technology, a new generation of instructional software is needed. A new framework, CaSA (Classroom and Student Achievement assessment), brings into focus the issue of matching teacher's goals and course objectives with students' learning and expectations.

CaSA is a flexible framework to augment the classroom experience by coordinating and synchronizing instructional streams, matching class plans to student class experience, and presenting instruction in a variety of media forms. Whereas many current e-classroom technologies augment course delivery or provide alternative means for delivery, CaSA will provide the means to assess and improve course delivery while providing alternative means for and augmenting delivery. The emphasis is on facilitating timely feedback, collecting assessment data, and offering alternatives to students with differing learning styles.



Preparation Component
Stream Definition Component
Course Outcome Definition Component
Real-Time Stream Component
Stream Synchronization Component
Stream Recording Component
Student Note Component
Student Feedback and Assessment Component
Review Component
Stream Review Component
Instructor Assessment Component

Figure 2. CaSA Component Diagram

The CaSA framework will consist of and coordinate three major components: a Preparation component, a Real-Time Stream component and a Review component (Fig. 2).

CaSA will support improved teacher effectiveness by providing immediate classroom feedback through collected student topic marking transmitted to the instructor as progress bars, periodic and frequent electronic concept questions both during and after class sessions, and instructional stream review and evaluation.

Pre-Classroom Preparation

Each lecture supports learning objectives from the course syllabus. Prior to the class, the instructor defines the lecture outline, covered topics, and the lecture notes (ClassPlan), which are associated with the text and course syllabus. The lecture consists of a ClassPlan presentation. As it is delivered, the various streams of presentation will be parsed into lecture segments, each of which is associated with a media type and descriptive

BEST COPY AVAILABLE

labels, such as 'introduction,' 'concept,' 'equation,' 'illustrative example,' etc. derived from the ClassPlan. CaSA will also permit streams to be added or removed interactively. As instructor presentation formats evolve, CaSA will accommodate these changes to electronically capture the class session.

CaSA will capture the data required to support creation of concept maps from the ClassPlans, the covered topics representing core concepts. As instructors and students connect additional material to these core topics, the data available for the concept map grows. There are several ongoing efforts in the area of visually representing concept maps including work by Puntambekar, Stylianou and Jin at the University of Connecticut (Puntambeker 2001) as well as work by Aroyo, Dicheva and Velev (Aroyo 2001). CaSA will collect the data required for concept maps and will facilitate the use of concept map representational systems within an e classroom.

In-Classroom Interaction

During the e-classroom experience, CaSA will coordinate instructional streams, assessments, and feedback and will electronically increase classroom interactivity. CaSA will connect classroom instruction to student feedback, collecting assessment data from student participation (topic marking, quiz and attitude testing), instructional streams, and instructor created course plans. Topic marking data can be used to provide instant feedback to the instructor and provide evidence that all required course topics have been covered during class sessions. Data collected from topic marking will not only be useful as to what topics were marked, but also when the topics are marked.

CaSA will electronically record the instructional content in its various forms, synchronizing the multiple instructional streams, as well as student feedback and assessment. It will provide context and valuable insight during assessment, instructor feedback, and student review.

The instructor's ClassPlan will be made available to students on their computing device at the beginning of each class session. This will accomplish three things. First, it will let the students know what topics will be covered, setting their expectations. Second, it will provide information needed for students to mark topics that will be covered. Third, it will document instructor intent which can them be compared to actual classroom experience.

As the class presentation proceeds, students will be able to indicate when they believe a specific topic has been covered. These marks will individually index the instructional streams. When they wish to review course material, the students can access the Web-delivered instructional streams based upon their individual marks. By allowing the students to use their individual marks to access course material, this system provides an incentive to mark topics as accurately as they can and serves to engage the students during the presentation.

As the students mark topics, CaSA will determine when and how many students believe that the instructor has covered a particular topic. This information will be made available to the instructor on demand as progress bars or via instant notifications based upon predefined thresholds. At a glance, the instructor can tell if students believe that a topic is or has been covered. If the instructor feels that he/she has presented a topic, but student thresholds have not been met, the instructor will know immediately and can make appropriate changes. The instructor will also be able to mark a topic as complete when a topic has been covered. Providing this feedback to the students will enable them to know immediately if they have missed important information.

Student topic marking also serves another purpose. Each student will be able to create personal links from personal material to course material, facilitating self-directed learning. By providing tools that assist students in retrieving, evaluating, comprehending and memorizing information while performing learning tasks the system will provide clear benefits. (Aroyo 2001)

CaSA will use the installed network of computers to permit the instructor to ask frequent, periodic questions to assess student understanding of the main concepts from the ClassPlan. Answers will be collected and immediate feedback regarding the overall state of student understanding can be presented to the student and the instructor. This will permit both student and instructor to take corrective action in a timely matter. In addition, reaction to and general attitude toward the material and class can be surveyed through positive and constructive questions during and at the end of the class.

Post-Classroom Review and Study

Stream review will be performed by students to assist in their self-directed learning, by instructors to critique and improve their material delivery, and by program administrators to insure that programs meet requirements. Also, independent evaluators can assess a course and by extension a program by sampling instructional streams and student topic marking data to verify that all the material necessary to support the course learning objectives was covered.

Questions from students are forwarded to the instructor through an intelligent FAQ (iFAQ). Replies to common questions that already have answers in the system's iFAQ are forwarded immediately to the student, while more elaborate or newer questions are sent to the instructor for a reply through email later. Each new question and its answer are added to the iFAQ and sent to the student automatically. The iFAQ assists both the instructor by filtering repeated questions and students by providing immediate responses to previously answered questions.

System Development

One goal of this system is to provide benefits to the instructor without putting a large preparation load on the instructor. The intent is to give an instructor an easy point of entry—minimal effort for maximum benefit. For example, by entering a course session outline into CaSA prior to a class session, the instructor will be able to publish the topics to students at the start of class, set their expectations for the class session, enable topic marking, stream synchronization and assessment stream data capture. All of this can be received by entering the topic outline, generally created during class preparation anyway, into the CaSA system.

The CaSA system is currently under development. Systems have already been created to provide adaptive learning and iFAQ (Gilbert 1999) and stream storage and playback services (from the UC Stream Media Group). However, these systems have not been integrated. Prototypes have been created to test student stream marking within a Windows Media Player stream and to integrate course topics with student notes.

Towards that end, the underlying software has been written using a layered approach to maximize reuse and interoperability. Figure 3 demonstrates a full communication cycle through presentation, client, clientRMI, serverRMI, server, and data base layers (Fig. 3). The plan is to have a working CaSA syaem with a sub-section of functionality available by the end of 2002. Additional functionality, including learning object support (Learning Object Metadata Working Group 2002) will extend CaSA in the future.

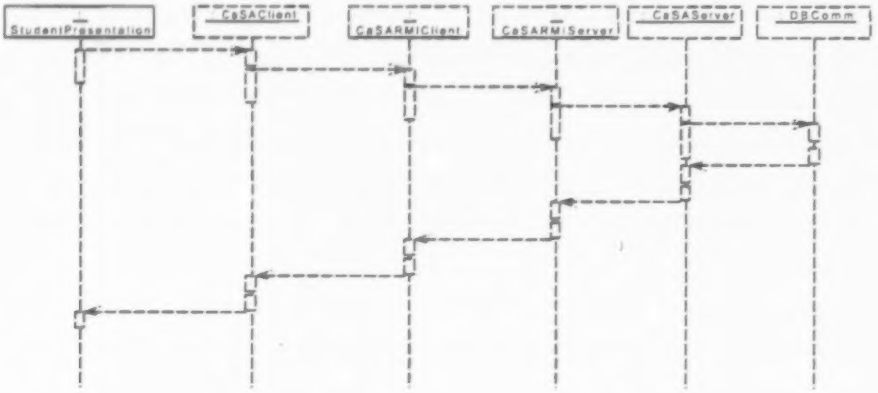


Figure 3: CaSA System Layered Communication Overview

Conclusions

E-classrooms, and CaSA in particular, provide a unique opportunity to augment the current classroom experience, aligning the expectations of students, instructors and institutions. Given a system where both instructional and presentational aspects of a lecture can be evaluated promptly, instructors, students and program administrators can react quickly when there is a gap between program requirements, course objectives and learning outcomes, between the intent of one and the understanding of another.

This framework will improve instructor effectiveness with prompt and iterative feedback, giving information and guidance regarding the kinds of educational materials and practices that most effectively enhance student achievement. It will also increase student engagement, providing an environment that produces demonstrable gain in student achievement.

By developing this framework within an e-classroom, information can be gathered to measure student, faculty and organizational achievement and to assist in improvement. Creation and implementation of projects such as this will track core learning topic coverage, connect course topic delivery with program and curricular goals, provide comprehensive assessment data streams, and produce tools, procedures and measures to assess student learning and achievement and the effectiveness of improvement efforts. Using technology to open clearly defined communication from students, instructors, and program administrators will close the gap from defined, delivered and received content and make "A Significant Difference" (Russell 1999).

Semantics for E-learning:
An advanced Knowledge Management oriented metadata schema for learning purposes

Mr. Miltiadis D. Lytras

Athens University of Economics and Business,
Department of Management Science and Technology, Greece
Email: mdl@aueb.gr

ABSTRACT

In recent years many researchers try to investigate the direct or indirect impact of knowledge management approaches to the achievement of strategic corporate objectives. Several approaches have been promoted, with main emphasis to be paid at the justification of knowledge exploitation processes (Nissen, Kamel et al. 2000), (Binney 2001), (Lee and Yang 2000), (John Garrick 2000), (Martensson 2000), (McAdam and McCreedy 1999). Our research effort is concentrated on the demand for high quality interchangeable knowledge objects capable to support dynamic learning initiatives. The general metadata models (Dublin Core, IMS, LOM, SCORM) for knowledge objects enrichment are been reviewed and a well justified critique is provided in order to claim the importance for the justification of an "interchangeable knowledge objects standard" for learning purposes. The overall objective is the justification of a dynamic learning environment capable of supporting the value diffusion.

Keywords: Knowledge management, E-learning, Semantics, Learning Objects Metadata

1.0 Introduction

The knowledge exploitation in modern era is recognized as a critical phenomenon. Several approaches (Kim and Mauborgne 1997), (Allee 1999) reveal the potential capacity of knowledge to empower the capacity for effective action. The development of dynamic learning environments requires a systematic justification of methods and processes that vary learning (unique value proposition) for every learner. In this direction a number e-learning techniques (Lytras and Doukidis 2000) (Ruttenberg, Spickler et al. 2000), (Bryans and Smith 2000) seem to be a common approach with uncertain performance (Lytras and Pouloudi 2001). This challenging situation sets a context that promotes the research in reusability of knowledge resources. A realization of reusability can be based on semantics that enrich general knowledge resources (e.g. an article, a journal paper, a PowerPoint presentation, e.t.c.). The ultimate objective is to expand the customization capabilities of learning environments,and knowledge management seem to be a well justified mean for the achievement of such a goal (Lytras and Pouloudi 2001), (Lytras, Pouloudi et al. 2002).

1.1 Reusability of learning content and metadata

A major problem in the learning industry is the inability of the dominant e-learning platforms to support knowledge management mechanisms (Lytras, Pouloudi et al. 2002), (Lytras and Doukidis 2000). This causes a number of limitations in the implementation of learning scenarios. Our research intents to justify a metadata schema and a correspondent logical schema in XML that support a dynamic e-learning environment. The current situation on metadata is described by a narrow vision on learning. The analysis of dominant metadata schemas that follows seems to be inadequate to exploit learning content.

Two basic problems concerning learning content are the codification and the diffusion. Traditional knowledge management approaches (Boisot 1987), (Hahn and Subramani 2000), promote critical guidance for the understanding of how these two problems can be solved. Diffusion basically incorporates two dimensions. The carriers of content and the learning scenario. Packaging of learning objects in operational modules or logical settings with relevant value for learners provides an integration of the two facets of key issues. XML language makes the packaging of learning content more flexible as it provides enormous capabilities for Document Type Definitions, or in simplest words a design language for the description of structure of documents or knowledge resources in general. This ascertainment, and the whole path of syllogism can be summarized in the following hypotheses:

H1: Is there a way for the enrichment of knowledge resources that parameterize a dynamic learning environment?

H2: Can we exploit the knowledge management theories of knowledge life cycles in order to present a constructive development of learning content?

H3: Can we justify a way for the packaging of learning content according to a knowledge activities perspective?

H4: Is there a metadata schema that is oriented to the knowledge activities and the learning exploitation?

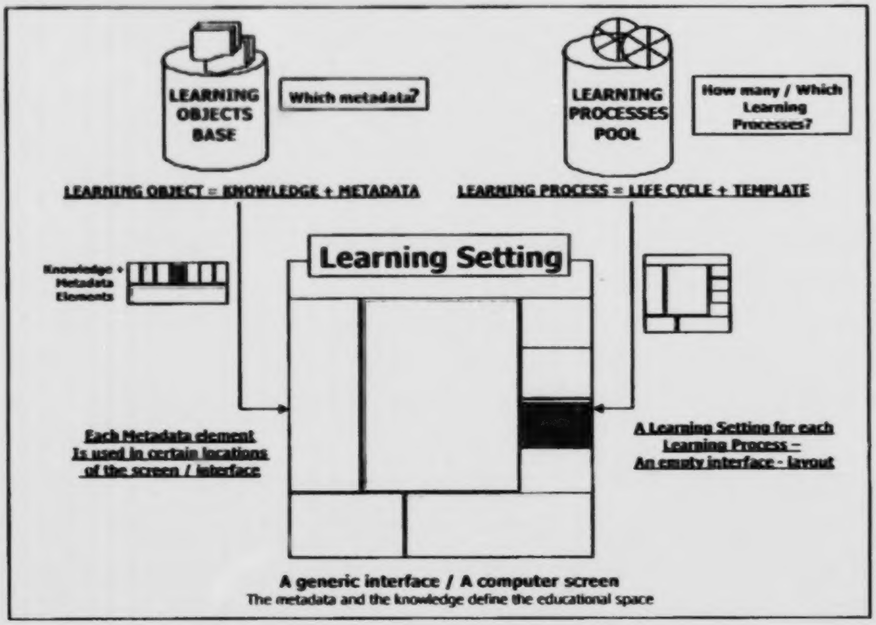
The case of reusability of learning content is an open issue for the academic community (Zack 1999), (Abecker, Aitken et al. 1998), (Mahé and Rieu 1998), (Tautz and Gresse 1999), (Mentzas, Apostolou et al. 2001). It seems that a hidden convergence formulates a holistic approach. The cornerstone in this approach is the description of a common standard that supports the enrichment of digital contents with metadata or semantics. Our research effort goes a step further. It investigates the justification of a learning objects metadata schema that innovates in two ways. First of all it elaborates the knowledge management theories and second utilizes learning objects hierarchies (Bloom and Krathwohl 1984).

2.0 A synopsis of conceptual abstractions

The organization of knowledge in distinct objects, small structural components, is the basis of reuse. In the case of customized learning the same learning content can be used in many ways due to its integration with other knowledge objects.

Our approach is based on two clear assumptions that initiate the whole research:
A learning object is a synthesis of knowledge and metadata that expand further the learning effect of knowledge. From this perspective an e-learning environment has to utilize a learning objects base. A critical question is which metadata can we use in order to increase the learning effectiveness. A learning process is an abstraction of a logical sequence of learning activities or tasks. The conceptualization of learning processes determines an interface in which the components of a learning object can be realized. This layout is a value container, which is utilized by the embodiment of learning object. The critical

question is which learning processes can we use? And is there any hierarchy of learning processes that determine different value layers.



LEARNING OBJECTS BASE
Which metadata?
LEARNING PROCESSES POOL
How many / Which Learning Processes?
LEARNING OBJECT = KNOWLEDGE + METADATA
LEARNING PROCESS = LIFE CYCLE + TEMPLATE
Learning Setting
Knowledge + Metadata Elements
Each Metadata element Is used in certain locations of the screen / interface
A Learning Setting for each Learning Process – An empty interface - layout
A generic interface / A computer screen
The metadata and the knowledge define the educational space

Figure 1: The basic conceptual abstraction

2.1 *Reusability of learning content and Knowledge Management Convergence*

The underlying issue behind the packaging of knowledge is the re veal of a key idea that will support the accomplishment of a metadata scheme. Our proposition that has been developed after many implementations of elearning projects in our research unit, ELTRUN. (www.eltrun.aueb.gr) is that the convergence of knowledge management and e-learning is realized through an integrated life cycle model. Each step in this model that is depicted in figure two represents a value adding process. Each step sets a context for questioning about the required metadata that have to be attached to a generic knowledge source in order to formulate learning object. The first cycle summarizes a general Knowledge management framework where 6 processes / activities (Relate / Value, Acquire, Organize, Enable Reuse, Transfer, Use) make possible the management of knowledge object. The second cycle stands due to the assumptions that learning requires a further adoption of general knowledge sources. The six processes of the second cycle in figure two justify a learning orienting enrichment. The engagement of learners with the e-learning environment is becoming true through the employment of a number of learning processes.

Figure 2: The Interchange Knowledge Flow

The key proposition in our approach is that a number of metadata can supports each step in the whole model and also the learning processes as learning objects containers. For the specification of the elements of this metadata scheme a review of well-known metadata schema has been undertaken.

2.2 Multidimensional Dynamic Learning Proposed Metadata Schema

Metadata are data about data (Brasethvik 1998), (Weitlaner 1999). In the context of learning, metadata are data about learning objects. This definition provides the major characteristic of metadata: They are descriptive indexing labels. Unfortunately for the case of learning this is not enough. The indexing of learning object it seems to be a management facility with limited impact on the realization of engagement of learners. A lot of approaches concerning metadata have been proposed for general or learning purposes. Some of the most well known organizations that work in metadata specifications are the Aviation Industry Computer-Based-Training Committee (AICC), the IEEE Learning Technology Standards Committee, the ARIADNE, the Educause Instructional Management Systems (IMS) Project, the World Wide Web Consortium (W3C), and the ADL. The need to specify metadata elements is translated to a two-fold requirement:(1). The specification of general metadata capable of supporting our theoretical proposition of general Knowledge Management Framework (see figure 2) and (2) the determination of metadata focusing on learning processes. The critical review of several metadata schemas including IEEE Learning Objects Metadata, IMS, Dublin Core, SCORM, GEM provides a rather superficial support for the second requirement and a sufficient support for the first one. The complexity of learning causes significant problems to the clarification of the practical dimension of what it means the achievement of different

BEST COPY AVAILABLE

educational goals. This gap in the propositions of the famous metadata schemas sets a context for significant contribution. The two advantages of the presented metadata schema s that cannot be explained further due to the limited space include:

(1). Shifts the key justification idea from indexing categories direct related to distinct roles or properties (e.g. Author, Technical Characteristics, Pedagogy) to value delivering processes (Knowledge & Learning Processes). (2). Provides advanced capabilities for extension. The 9 learning processes specified based on the work of Bloom (Bloom and Krathwohl 1984), and Tom Shuell are only some of the learning processes that can be modeled and used. For new learning processes modeled are required a number for new metadata schema elements.

If we justify the two sets of metadata then we can define in XML structures every knowledge resource. Potentially each knowledge resource can be enriched using a all the specified metadata elements. It can be also enriched to a limited extend. This incremental approach where a general knowledge resource can be exploited through the attachment of metadata secures a dynamic elearning environment.In the next section two tables present the proposed elements of the Multidimensional Dynamic Learning Metadata Schema. The first table summarizes the general metadata elements derived from a critical synthesis and evaluation of four famous metadata approaches. The second table summarizes the metadata elements that support the defined learning processes.

The usage scenario of these proposed metadata elements includes the manipulation of general knowledge sources and the attachment of all the required metadata. It is easily understood that potentially a knowledge provider can provide the whole metadata set accompanied to a resource. The learning process that will finally became the value driver and the mean for the diffusion of learning objects will specify the subset of metadata that will fill the layout of the specific learning process. It is obvious that the acceptance of this approach requires enormous efforts from the knowledge providers. This seem to be the most critical success factor since the dynamic development of a learning scenario requires the selection of some learning processes that deliver learning objects to the trainees. The next three tables provides a synopsis of the 3-level metadata specifications.

Metadata for general KM life cycle	
Relate / Value	Language, Subject, Quality, Main Concept

3.0 Conclusions

The overall approach described in the limited space of this paper provides a context for exploitation focusing on learning. The incremental refinement of conceptualization drives to a set of metadata that can assist the transformation of knowledge resources to reusable learning objects. This step-by-step justification finally drives an extensive XML specification of the metadata schema. The selection of learning processes as the carrier of value expands the dynamic nature of an e-learning system. The whole approach seems to integrate the two well-defined and distinct approaches to knowledge management, the knowledge artifact and the knowledge activities approaches. Future research is concentrated on the analysis and the development of a dynamic e-learning environment based on the key ideas of Knowledge Interchange Concept. For this scope an IST proposal is going to be prepare. We welcome any collaboration that will support the refinement of this proposal.

Abstract: This paper focuses on the authors' experiences with interactive, synchronous internet video conferencing using Microsoft's NetMeeting software with deaf and hard-of-hearing students in two different settings. One setting involved teaching and tutoring computer programming to remote deaf and hard-of-hearing students in a remote situation using synchronous Desktop Video Conferencing (DVC) using Logitech cameras mounted on the computer of each participant. A second setting involved the use of NetMeeting by deaf and hard-of-hearing students enrolled in an Internet Communication course. Students in this course were introduced to the various communication tools contained within NetMeeting and provided with experiential lab activities designed to simulate the work environment and facilitate communication with hearing colleagues. In addition, online office hours were offered to provide additional experience with NetMeeting and promote access from remote locations.

Introduction

In the past, distance learning with two-way video was out of reach for many remote students and institutions. Recent innovations in telecommunications have lowered equipment and transmission cost, making two-way desktop video feasible for businesses, classrooms, libraries, and even homes. In the education of deaf students, video conferencing is also becoming more prevalent due to the inexpensive pricing of desktop cameras and hand-held camcorders as well as the increased access speed at which the deaf and hard-of-hearing audience is accessing the Web. The terrible events of September 11th have also discouraged travel and encouraged the use of remote interactions.

In this paper, the authors share their experience in two different arenas. One area is teaching computer programming courses to deaf and hard of hearing students in remote locations. In these courses Desktop Video Conferencing (DVC) was used in remote, synchronous tutoring sessions. A second area where DVC technology is being used extensively is in instructional efforts designed to facilitate communication between deaf, hard-of-hearing and hearing colleagues in the workplace. Through the use of DVC technology, communication barriers imposed by traditional telephone technology can be overcome to facilitate communication and collaboration. Knowledge and experience gained by deaf and hard-of-hearing students enrolled in the NTID Internet Communication course can be directly applied to the workplace to enhance communication.

Affordable broadband connections and technologies at home, work and school are rapidly growing. These high-speed connections are changing the capability of carrying large amounts of text, voice and video data over existing telephone and cable lines. Microsoft summarized the technology in a very concise manner: "For years now, computer networks such as the Internet have been carrying text-based messages around the world. Most often, these messages take the form of electronic mail, though real-time chat programs are also used. As the quality and speed of computer networks increase, so do demands for higher levels of interaction that include voice, graphics, and video exchange in real-time. This growing trend toward richer communications via computer is known as Internet Conferencing." (Microsoft, 2001, USA-L_News@yahoogroups.com)

Various researchers have investigated the transmission of sign language, which features significant motion of the arms and hands, and requires a frame rate high enough for smooth motion perception (Schumeyer, Herrdia, & Barner, 1997). Science teachers such as Mary Ellsworth at the Model Secondary School for the Deaf in Washington, DC (http://csc.gallaudet.edu/soarhigh/SHMAHOM.HTM), have also previously experimented with computer-based videoconferencing over ISDN lines. Such research and instructional efforts are pioneering. Educators of deaf students eagerly await progress with the new technologies.

The Study

The experiments reported in this paper were action research projects conducted in search of ways to enhance distance learning. The "findings" are thus tentative and provide suggestions for more formal research.

Synchronous Tutoring in Distance Learning Computer Programming Courses

Most of the Distance Learning (DL) courses at Rochester Institute of Technology (RIT) and the National Technical Institute for the Deaf (NTID), one of RIT's colleges, have focused on asynchronous (any time, any place) delivery of instruction. After teaching multiple remote, DL computer programming courses to a deaf and hard-of-hearing audience, however, it was found that both synchronous and asynchronous types of online instruction are necessary for some students to have a successful distance learning experience.

One author tutored remote deaf and hard-of-hearing students via a QuickCam Desktop Camera in conjunction with Microsoft's NetMeeting as an asynchronous tool for clarifying concepts with one deaf student and one teacher. This is often referred to as point-to-point video conferencing, where only two people can talk and see each other at a time. Although this hardware and software can easily incorporate group conferencing of remote students by the instructor, the project reported on in this paper involved only point-to-point video conferencing. The students selected were tutored on an individual basis in a credit-bearing DL course in Visual Basic Programming.

Desktop Video Conferencing (DVC) is one of many different types of conferencing tools. The DVC components include a video conferencing camera, such as the QuickCam camera used for this project, an Internet telephony application, a microphone, and speakers mounted to the local computer (the microphone and speaker built into a laptop computer were found to be adequate). DVC links two or more participants at different sites by using computer network(s) to transmit data. DVC is based on Codec (compressor-decompressor) technology. A Codec works via a mathematic computer algorithm to compress and decompress digital data. The data can be video, audio, or text based. A Codec is an important part of any Internet telephony application such as Microsoft's Netmeeting.

To use Desktop video conferencing, the student and instructor both need to have a computer, a camera, and an Internet connection to send and receive the video. From the authors' experience, the computer should be a Pentium-based PC running on Windows 95, 98, NT or Windows 2000. The authors have no experience with the new XP, Linux or other operating systems yet. The faster the processor speed the better the video will run. All the Pentium based processors are more than adequate to handle DVC. The user should have at least 32 MB RAM, although more memory will be better, especially if the user plans to have other applications open when using DVC. The PC should have enough hard disk space for file swapping; at least 20 MB would be a minimal requirement. A video capture card is also necessary.

The Internet connection for conferencing should be as fast as possible. It is recommended that both users be connected at speeds much faster than the Plain Old Telephone System's (POTS) 28.8 kb per second. A Local Area Network (LAN) with RoadRunner™, Integrated Services Digital Network (ISDN™), the Digital Subscriber Line (DSL™), or T1 connection would be optimal. Temasek Polytechnic does an excellent job of laying out system requirement and step-by-step instructions on how to set up DVC on their website. (Temasek Polytecnic, 2001, http://eicu.tp.edu.sg/DVC/index.htm)

The camera chosen should be a desktop type of camera that easily interfaces with the computer. Although the QuickCam had many features for storing photographs, it was the video feature of the DVC and the low price that was the most appealing for the project discussed in this paper. The QuickCam camera is capable of recording video at up to 30 frames a second.

NTID Telecommunications Curriculum

NTID has a long history of providing technical and communication training to deaf and hard-of-hearing students. Initially, curriculum designed to provide communication training in the area of telecommunications focused exclusively on the use of traditional telephone/TTY technology to facilitate remote communication in the workplace. In more recent times, with the advent of DVC and text-based communication technologies utilizing the Internet, curricular offerings have expanded to reflect the vast array of technologies that are now available to facilitate communication between deaf, hard-of-hearing, and hearing employees in the workplace.

DVC technology has been a major component of the NTID telecommunications curriculum since the early to mid 90's. At that time, instructors began experimenting with a beta version of Cornell University's CU-SeeMe videoconferencing software. When used in conjunction with a grayscale Connectix QuickCam and Ethernet connection, students were able to place point-to-point videoconference calls throughout the world via the Internet. As an example, calls were regularly placed between deaf students at NTID and those attending the Tsukuba College of Technology in Japan. Although quite unsophisticated by today's standards, this technology opened door for deaf and hard-of-hearing students seeking employment by providing an inexpensive means of facilitating communication through the use of real-time video and text-based chat.

A survey of students conducted at NTID revealed many positive attributes regarding this technology (MacKenzie & Clymer, 1999). In particular, students commented on how DVC allowed them to visually identify a caller and gain information on their mood and emotions by analyzing facial expressions and body movement. In addition, they found it extremely beneficial having both video and text-based chat available for real-time remote communication.

Since then, several newer DVC systems have been incorporated into the NTID telecommunications curriculum for students to evaluate. Of these, NetMeeting has quickly become popular among students since it offers an inexpensive means of establishing point-to-point videoconference calls. As part of NTID's Internet Communication course, students are introduced to NetMeeting and its wide array of communication/collaboration tools including video, text-based chat, file transfer, whiteboard, and application sharing capabilities. Through the use of structured lab assignments designed to simulate situations common to the workplace, students gain first hand experience with NetMeeting with the ultimate goal of enhancing communication and collaboration with their hearing colleagues. Instructors have also begun offering online office hours using NetMeeting, provide students with additional opportunities to evaluate the software and promoting greater access for those who desire to discuss course information or review class assignments outside the traditional class schedule.

Conclusions

DVC is both inexpensive and easy for instructors and students to implement. The technology significantly enhanced remote tutoring sessions by making remote interactions more personal. Communication with the deaf and hard-of-hearing relies heavily on facial expressions, body language and gestures. DVC, when combined with the other tools mentioned in this paper, provided an adequate environment for successful remote tutoring sessions.

In distance learning tutoring for the deaf and hard-of-hearing, DVC is often too slow and choppy for fluid, extended sign language conversations, but it does allow the sharing of some limited sign language, gestures, facial expressions and body language. This real-time interaction significantly enhances chat sessions and white board viewing of instructional material such as text explanations or computer program source code. Netmeeting also allows the use of highlighting and drawing on top of instructional materials, which can easily be posted on the online white board or even saved later in an electronic conference.

Video conferencing is becoming more affordable as use of broadband connections and technologies such as ISDN, DSL and Road Runner at home, work and school increase. These high-speed connections will change the capability of carrying large amounts of text, voice and video data over existing telephone and cable lines. Videoconferencing systems also incorporate compressed digital video. This compression technology makes the transmission of video less costly by reducing the size of the video needed to be transmitted.

Broadband access has also impacted DVC and other types of video conferencing. A survey taken last year of 2000 online RIT students, of which 50 were deaf, gathered a 10% response rate and found that 70% of these students had access to broadband Internet access at home, work or school. (Fasse, 2000) Of the 20 respondents to a fall , 2001 academic quarter survey of exclusively 33 RIT deaf and hard-of-hearing online students, 85% of these learners had access to high-speed internet access while 100% of all on-campus students have capability to this access. (Mallory, Long, 2001) According to AOL, Americans with online access has increased from 45 million users in 1998 to 105 million users in 2001. Of these online users, those with home broadband access has grown from 6% in December, 1999 to 19% as of September, 2001. (Mount, 2001, pp. 44-45) This shift in the access speed of the student population makes video streaming an increasingly viable option for delivering synchronous communication and instruction.

Desktop Video Conferencing (DVC) is a widely available, low cost, practical technology that can be used in synchronous, online tutoring/teaching sessions. Although the limited throughput on the Web makes it challenging to observe sign language in a fluid and practical manner as a primary instructional or conversational tool in online courses, it has been useful as one means of tutoring remote deaf students when used in conjunction with a complete DVC package. A DVC package with a desktop camera allows the sharing of some sign language, gestures, facial expressions and body language. This real-time interaction significantly enhances chat sessions and white board viewing of instructional material such as programming code. Netmeeting also allows the use of highlighting and drawing on top of instructional materials, which can easily be posted on the online white board along with a chat session interaction.. When the DVC video was combined with Microsoft NetMeeting's other features, the total package was found to be an excellent communication and instructional tool.

The hardware, software, and Internet connections are now available to provide a complete Internet conferencing solution such as DVC at a very reasonable price. DVC incorporates the use of desktop cameras and software that can provide an adequate environment to perform remote, synchronous tutoring for deaf and hard-of-hearing students. With the increase in digital compression technology and students increased connectivity at high-speed, broadband access speeds, use of digital video conferencing will continue to grow.

Abstract: This paper reports on a 2 year exploratory study to determine the viability of voice-based threaded discussion forums as a means of stimulating discussion and understanding of weekly readings as part of a large undergraduate communications course. It was found that most students preferred to make text rather than voice postings. The factors contributing to this preference are examined and discussed and recommendations for further research are made.

Introduction

It is often difficult in an asynchronous online environment to express ones thoughts using text alone (Kouki and Wright 1999). Ong (Ong 1982) in his study of orality vs literacy argues that oral communication requires a different and more extensive use of thinking which is more immediate compared to text. Often text is inefficient in expressing ideas quickly. Asynchronous online communication has been predominantly text-based until recently. This was out of bandwidth limitations rather than any pedagogical or communicative imperatives (Palloff and Pratt 1999; Pettit 1998)

Now that we are in a position to use voice-based asynchronous online tools in educational contexts it is important to begin trials and evaluations to determine how to make the best use of these tools. This paper presents the results of an exploratory trial of voice-based discussion forums over a 2 year period (2001–2002). The objective was to determine whether voice-based discussion forums were viable as a means of stimulating discussion and understanding of weekly readings as part of a large undergraduate communications course.

The study reported in this paper is influenced by Donald Shon's 'Reflective Practitioner' approach (Schön 1991) as part of an overall Action Research strategy (Kemmis and McTaggart 1988) . "How you see the world is largely a function of where you view it from, what you look at, what lens you use to help you see, what tools you use to clarify your image, what you reflect on and how you report your world to others." (Anderson and Arsenault 1998: 3)

Method

In March to June 2001, 600 Students participating in a large introduction to communication course at the University of South Australia were required to post a summary of their readings each week to a threaded online voice/text forum. Forums varied in size from 20 to 80 participants. The intention was to provide an incentive for students to complete required readings before each weekly tutorial and to stimulate discussion.

The course is delivered face-to-face with considerable online support. The course is constructed according to principles of active learning (Brooks 1997, Forsyth 1998, Palloff and Pratt 1999).

Wimba Voice Board software (www.wimba.com) (fig 1) was used to facilitate the forums. This software has both a client and server component. The server component was installed on a server at the university. Participants then connected to the server through a web browser and automatically downloaded the client software which ran embedded in their web browser. The client installed seamlessly into most participants' web browsers.

This experiment was conducted in a context where participants are computer literate (to at least a basic level), predominantly young, and motivated to participate. Participants could choose to make contributions to the forums in either text or voice or a combination of both. Text was input through the keyboard. Voice was typically input using a microphone/headphone headset through the computer's sound card. Participants could make contributions from any location on the Internet. For most participants the choice was between using computers at university or a computer at home. All participants were required to purchase headsets prior to commencing the course.

Information on the usage of the forums was gathered by examination of server logs and a questionnaire survey of participants at the completion of the trial. The survey administered online and was voluntary and

anonymous and all members of the cohort were invited to participate. A response rate of 154/582 was achieved.

We noticed that, over time, as participants used the forums, the frequency of text postings increased with a proportional decrease in the frequency of voice postings. We wanted to explain this difference and this provided the motivation for this study.

In 2002, the experiment was repeated with the next cohort of 587 students (response rate of 124/587). These students used voice forums in exactly the same way as the previous year's students with the exception that they were not shown or informed about the ability to use text or a combination of text and voice. Consequently all postings to the voice forums were voice-only in 2002. It was our belief (Marriott 2001) that given sufficient experience with voice posting, students would be more inclined to use this method of posting.

Results

Server logs

In 2001, according to the server logs, participants made 3943 postings with a voice component compared to 2392 postings with a text component. Postings with a voice component were clearly more popular.

Participants consulted text postings 25463 times and voice 11313 times. So while the voice postings were more numerous it was far more common for participants to read the text postings of other participants.

In 2002, participants made 5839 voice postings compared with 132 text postings. It is likely that these text postings can be attributed to headings posted by tutors to organize their groups. It would be reasonable to say that no students posted a text posting in 2002. Clearly the policy of silence on the ability to post text had a significant effect.

Survey

At the completion of the trial period all participants were surveyed using a questionnaire containing 5 Likert scale questions and 2 free response questions.

Fig 2 contains the 5 Likert scale questions that were given to both the 2001 and 2002 cohorts. The charts are arranged for easy comparison of groups. It should be noted that no attempt has been made to test for statistical differences between groups. Samples were not randomly selected and no information is available about differences between the 2001 and 2002 populations. Despite these limitations the charts provide an interesting basis for discussion, in keeping with the interpretive nature of the study.

Participants were also asked to explain why they preferred one method of posting over the other in the form of 2 free response questions. Table 2 is selection of representative responses to the 2 free response questions given to both the 2001 and 2002 cohorts. In this case only 2002 responses are given. The intention is to give an indication of the range of responses received. Analysis of free responses is given in the discussion section of this paper.

Fig 2: Likert Scale Questions: Voice Forum Survey

SA = Strongly Agree, A = Agree, N = No Strong Opinion, D = Disagree, SD = Strongly Disagree, NA = Not Applicable

Sample size (n) 2001 = 154, sample size (n) 2002 = 124; population 2001 = 582, population 2002 = 587

Question 1: I found the Wimba Voice Forums easy to use

	SA	A	N	D	SD	NA
□ 2001	25	60	12	1	2	
■ 2002	24	58	11	6	1	

Question 2: I like posting to the Voice Forums each week

	SA	A	N	D	SD	NA
□ 2001	5	20	38	24	10	2
■ 2002	6	25	37	22	10	

Question 3: I think the Voice Forums are a useful part of the course

	SA	A	N	D	SD	NA
□ 2001	8	42	33	12	4	1
■ 2002	10	40	32	11	6	

Question 4: I would like to use Voice Forums more in my studies

	SA	A	N	D	SD	NA
□ 2001	4	21	38	23	12	1
■ 2002	3	23	32	27	15	

Question 5: I would prefer to post text rather than voice messages

	SA	A	N	D	SD	NA
□ 2001	36	32	17	11	3	1
■ 2002	26	28	20	19	7	

Table 2: Sample of survey free responses

Date	The Wimba voice forums allow postings to be made as text or voice or a combination of both. In this course students made mainly voice postings. Which would you prefer to post, text or voice or a combination of both?	Why did you prefer one type of posting (voice / text)? Give reasons.
2/05/2002 10:22:53 PM	Mainly text, but voice is OK if REALLY necessary.	Probably because I become very self-conscious when recording my own voice. It is much easier for me to type it, erase it, re-type it ad infinitum, until I get it just right. As well as that, to have an effective voice posting you need the Uni's LAN connection. To do it from home is VERY slow and inefficient.
3/05/2002 7:35:04 AM	text	to me, it is more anonymous, and is easier to edit the information so that what you actually post is full of relevent information rather than um's and ah's.
3/05/2002 8:28:24 AM	Text only	You can think out your postings more with text entry. Even though the technology for voice messages is here now I believe that it is not fully evolved, which makes for on some occations hard to hear messages.
3/05/2002 8:40:52 AM	text.	I prefer text by far because I type much faster than I would speak on the Wimba voice forum. Also, when we were required to listen to other student's postings, their voices were sometimes unclear or hard to understand. Text is much easier in this respect!
3/05/2002 9:00:08 AM	Text	Easier to do, doesn't take up much of your time.
3/05/2002 9:43:27 AM	voice	it is easyer to use and faster.
3/05/2002 10:36:23 AM	either,or a combination	I was a bit shy to post voice messages when there were lots of strangers in the room, also voice messages sometimes needed to be redone because I didn't do them properly or there was lots of background noise, text eliminates these elements, but text is less fun too

BEST COPY AVAILABLE

Discussion

In the analysis of the 2001 results (Marriott 2001) it was clear that by the end of the trial most students preferred to post text messages. And while nearly all students initially posted voice messages, most drifted back to text. It was thought that many of the students had not given voice a fair go. Perhaps, we mused, if only they had persevered for longer with voice, they may have developed a greater preference for it. In 2002 it was decided to put this assertion to the test. Student in 2002 were not told of the Wimba software's ability to post text messages. Consequently all student postings in 2002 were voice-based.

Fig 2 shows the remarkable similarity between the 2001 and 2002 groups on all questions. In particular questions: 1 'usability', 2 'like making postings', 3 'useful part of studies' have almost identical distributions. Question 5 which deals with the preference of text over voice is slightly skewed in that the 2001 group seem to have a slightly stronger preference for text. Question 4 which deals with the preference for greater use of voice forums shows a slight tendency for the 2002 to want less future involvement with voice forums.

Our first concern was whether participants found the software difficult to use. We wanted to know whether the design of the software was a significant influence on the decision to post in text or voice. Question 1 (fig 2) shows that most participants found the software easy to use with no participant claiming the software was difficult to use.

We found the response to question 5 quite surprising, after all these students had never tried a text posting to the Wimba Voice Forums, yet the majority wanted to post in text. It seems that regular experience with voice-posting does not change the preference for text -posting in this context.

Responses to the free response questions (table 1), which probe deeper into the reasons why participants prefer voice, text, or a combination of both, are very similar for 2001 and 2002.

For a great many of the participants it would seem that voice-posting presents a challenge in that it:

- is embarrassing to talk into a computer in public or private
- is difficult to make long responses without errors
- is difficult to speak fluently
- is difficult to correct errors
- requires additional equipment (headset)
- presents technical problems on some computer systems

Those participants who preferred voice-posting see the benefits of voice as:

- a more natural and therefore easier way to present ideas and respond to the ideas of others.
- it is a richer means of communication that includes verbal cues and an emotional context.

Conclusion and Implications

The similarity between the 2001 study (Marriott 2001) and the subsequent 2002 study tends to provide validation for the initial findings. A small number of participants preferred to post voice over text. What is not clear are the factors that influence this decision. Familiarity with voice, alone, does not a likely factor. What is it that makes these participants different? This surely provides the impetus for a more focussed study that looks closely at people who prefer to post voice and attempts to uncover the contributing factors.

It may be that the context for the postings inherently is better suited to text and the participants are only responding to this environmental pressure. Perhaps certain types of asynchronous discussion are best done with text and others with voice.

What is not considered in this study is the effectiveness in terms of learning, of conducting a voice versus text asynchronous discussion. Does, for example, text or voice-posting provide deeper learning (Ramsden 1992)? Is this dependent on the context (Brown 1989)?

Abstract: The aim of this project is to build software development environments for teachers, enabling them to produce their own educational applications for their classrooms as easily as they might produce educational materials using a word processor. As one of means of realization of this goal, we have proposed a componentware methodology, and have developed fifteen components and three application programs for English as a Foreign Language, and presented the result (at ED-MEDIA 2002). We have continued researching componentware methodologies, and have created a wide variety of new components, categorizing these components into two main groups: basic components and high-level components. Basic components allow teachers to develop complicated CALL applications with a few simple programming statements. High-level components are, for example, independent applications not requiring any additional coding tasks. In this paper, we will describe 1) the background of the project, 2) advantages of componentware methodology, 3) past results, 4) basic components and high-level components, 5) Example applications made using our components , 6)a discussion of related issues and, 7) concluding remarks.

Background

Although a large number of computer-based teaching materials currently exist in the marketplace, these materials are not prevalent in the classroom (MEXT, 2001). One important factor contributing to their lack of use may be that these materials are designed to suit the largest common-denominator of students, and thus are often unsuited to individual classroom requirements, as instructional methods (and student comprehension) are highly variable and specific to each unique educational and curricular environment.

If a teacher were able to develop teaching materials on a multimedia computer in a manner similar to the development of more conventional teaching materials, such multimedia teaching materials would be more easily and thus more frequently implemented. Most teachers are acquainted with their students' abilities, and would be able to develop multimedia teaching materials corresponding to their students' needs, if minimal-to-zero programming knowledge on the teacher's part were required. As a solution to the current dilemma, we are proposing a componentware methodology. In the following section, we will describe the advantage of componentware methodology in contrast to more traditional authoring tools many teachers are currently using in order to produce teaching materials.

Advantages of componentware methodology

In contemporary education, many teachers are using authoring tools such as HyperCard and Toolbox in order to produce teaching materials. These authoring tools provide users with software-routines encapsulating some features enabling users to handle graphics and text. By using these software-routines, teachers can produce their own teaching materials. However, such authoring tools have some severe limitations. Some of these limitations are: 1) they require some programming ability, 2) they cannot provide us with new software-routines and do not allow us to change features of their software-routines in order to fit a specific purpose, and thus, 3) it is difficult to implement in software the rapid changes in multimedia technology, and in addition 4) such programs sometimes force us to re-work teaching materials whenever upgraded or entirely new versions arrive.

Componentware methodology has a great potential to overcome the above-mentioned limitations. Componentware is an object-oriented software development method which uses and integrates components as essential building blocks (Aoyama, 1996; Jacobson et al., 1995; Udel, 1994). Componentware methodology allows us to develop software systems in both a top-down and a bottom-up fashion. This is an essential aspect of educational software systems development. The bottom-up approach can allow a teacher to easily develop a new educational software system by assembling pre-existing components. In the case where a teacher wants to develop a new type of teaching material, the top-down fashion can be adopted to break down a teacher's requirements into functionally modular components. Another advantage of the componentware methodology is in meeting requirements for computer usage in the real educational world: We can categorize teachers into three groups: an advanced group able to develop original program components, an intermediate group able to assemble pre-existing components into educational software, and a beginner group who can use pre-existing educational software systems in their classes. The advanced group develops components, making full use of their specialized knowledge and provides them to the intermediate group; the intermediate group is able to make educational software by using given components (i.e. they can produce specialized software systems without specialized knowledge); and the intermediate group is able to provide educational software to the beginner group—the beginner group is then able to make use of the educational software in their classes. If this flow from the advanced group to the beginner group is made to function smoothly, computer-based education can become more effectively and easily implemented.

Past Results

We have developed four component-based software applications and fifteen reusable software components for English as a Foreign Language (EFL) education (McCarthy, Matsuno and Swan, 1996; Matsuno, Tsutsumi, and Ushijima, 1999; Gilbert and Matsuno, 2000a and 2000b). In the EFL field, teachers have not only been using multimedia devices such as tape-recorders, CDs and videotapes, but also have been using computers since the advent of the institutional computer lab. In this field, therefore, multimedia computer systems and software offer a significant contribution to education

In a pilot study, three beginner-programmer students produced EFL applications using componentware components. They were all able to produce EFL applications with sound and movie clips as easily as producing EFL educational materials using, for instance, word-processor software, after they were given instruction on the usage and programming of each component. (Instruction occurred within one 90-minute class.) There were some common themes in the students' software products, exemplifying typical EFL materials—for example a "listen-and-repeat" practice-program, Japanese/English bilingual-switching dialogue program, etc. While these were useful products, additionally the students had wanted to produce evaluation tools documenting the learning-effect. But these types of components (e.g. quiz-type or questionnaire-type components) required more challenging programming structures. There are three typical program structures for combining statements in a program: sequencing, conditional(if statement), and repetition(loop). The students used only the sequencing-structure component-types, and had difficulty using conditional- and/or repetition-structures. In this situation we were faced with two possibilities. The first was to instruct the students on conditional- and repetition-structures. A second possibility was to create some mechanism that would enable students to produce evaluation components without the necessity to code with conditional/repetition structures. As we have mentioned, the aim of this project has been to build software development environments enabling teachers to produce applications as easily as producing educational materials using a word processor. With this in mind, we examined our existing components, and classified them into two categories: basic components and high-level components. Both component-levels now include encapsulated conditional/repetition structures (which no longer require extra coding of these structures by the student). The difference between the two levels is that the high-level components are actually a conglomerative integration of a number of basic components, thus are oriented towards the beginner programmer (they are close to being stand-alone applications). In the following section, we will describe both basic components and high-level components.

Basic components and High-level components

Basic components (Fig. 1) allow teachers to set or change the required properties and parameters of each component during the design-stage as well as at any time the program is used. As well, the program does not have to be "run" in order for the properties to be confirmed (usually any change in design is seen immediately and visually). This means that since teachers are able to set and confirm many properties (e.g. "font color", "caption title", "audio-file filename") without programming, they are able to produce complicated applications using only a few simple lines of programming code. As well, teachers can change or set properties dynamically.
The intermediate group is able to produce higher-level applications by joining a variety of components together, using their more advanced programming skills. High-level components (Fig. 2) are component frames, and include several individual components. Both the properties and the more complex linking routines of high-level components are set in advance by the component builders (our componentware research team, or similar advanced programming group). Therefore, the beginner group can produce an application program with no programming requirements, and the intermediate group can produce a great variety of applications with the addition of extra components/frames and/or by adding new application behaviors by using inherited features of object programming. This is similar to cooking a frozen pizza. Even though you have no idea how to make a "scratch" pizza, you can microwave a frozen pizza in a few minutes by following some simple instructions; this enables you to eat pizza quickly and easily. If you have even modest cooking skill you can add some toppings, etc., prior to the actual cooking process for a more delicious frozen pizza. It may be noted that on occasion, even a talented (perhaps hungry) chef may wish to save time and effort by cooking a frozen pizza.

Basic components

Multimedia Components

The "Multimedia Components Group" is a set of components allowing teachers to use multimedia files easily. We will introduce MMLabel (Fig. 3), one of the multimedia-group components, as an example. MMLabel is helpful when a teacher wants to produce, for instance, an English Learning program for students whose mother-tongue is Japanese. Since MMLabel has two captions and a multimedia filename property, the teacher can set the English dialog text to caption1, a parallel Japanese translation-text dialog to caption2, and designate an English sound/movie clip filename (for example showing the teacher speaking). This process requires very little design time to implement. Now, all that the teacher needs to do is just press the "Run"-button. Students are able to see the caption1 text of the MMLabel component with the English dialog on the screen, and when they click on the MMLabel, they will listen to the English dialog or will be able to watch the movie clip. The teacher can use as many as MMLabels, as they wish, and can thus produce a conversation-practice program without coding. In case the teacher wishes to show students the corresponding Japanese dialog, the teacher only needs to write one line

Fig 3. An Example Application made using MMLabel

of simple code: "MMLabel.caption:= caption2". In the case of a teacher who has even modest programming ability, a variety of programs can be created in a like manner.

Communication Components

Communication components allow a teacher to make communicative programs such as their own browser and chat programs. The browser component is made using Microsoft's IE-engine. The Intermediate group can make their own browser by using the IE-Engine, but there are still difficulties for the beginner group. A similar

BEST COPY AVAILABLE

situation is faced when beginners try to make their own chat and mail programs. However, even the beginner group can make these types of programs very easily within the componentware environment. Additionally, since componentware browser components can show web pages in a specified order and at specified intervals, teachers can easily incorporate slide shows into their program materials.

Database components

The Database components group is a set of compound components handling multimedia and internet functions. We will introduce the MMTable component as an example. This component allows for the concurrent use of several different events, for instance: the display of a caption, display of an image, playing of a sound/movie. As well, this component can convert selected database elements into html form. The MMTable component has two important properties for easy database programming, a DatabaseName and a MultimediaField property. All a teacher has to do is set the database-name property to a DatabaseName parameter, and set the database field parameter of the MultimediaField property during the design phase. For example, set DatabaseName to "English Media" and set the multimedia field property to "Record I". The teacher can then use the specified database elements, and can additionally create new elements if necessary, without needing to re-design their program.

Utility Components

When making educational programs, we have observed that similar functions are often utilized (for example: shuffling/randomizing, delay-interval timer, kanji-to-kana converter). Utility components are sets of such small "gadget programs" for coding educational programs. Taking one of the utility components, a shuffle component, as an example, this component may be used when a teacher makes a quiz program. Students may memorize the location of the correct answer from a multiple-choice question if the same quizzes are repeatedly given to them in same order. With the shuffle component, the teacher can produce quizzes which randomize the correct answer within a larger set of wrong answers and show the correct answer out of a subset of multiple choices (say, one correct answer in four available choices), at random, with very little required coding.

High-level components

High-level components are made by assembling basic components. The target group for the high-level components is the beginner group, and each higher-level component is additionally able to function as a standalone application when it is compiled. The advantages of providing such programs as component sets, rather than as finished applications is as follows:

1) To be able to modify layout and properties as an individual teacher prefers, which can thus provide teachers with fulfillment of their specific pedagogical goals.
2) To be able to add new features by integrating additional basic components.
3) To be able to modify the behavior of the components with inherited functions of object programming.
4) To be able to produce an application program of their own design by putting together one or more high-level components.

We would like to restate two important points, mentioned above: 1) high-level components are, virtually, standalone applications, and 2) in a componentware approach the overall process should be focused on a specific educational field. Therefore, we focused on EFL (English as a Foreign Language) education, which often utilizes computers for educational use.

We have six types of high-level components now. Three of them can be used for creating Web-based quizzes (these three components can be used not only in EFL fields, but in other fields as well). Two of these components can be used for creating TOEFL(Fig. 4) and TOEIC practice programs, and one of the components can be used for creating a presentation program (which allows for slides, sound/movies and simple animations).

Fig 5. An Example of Application Programs made by students

BEST COPY AVAILABLE

All of these components are assembled with database components, but teachers do not have to have any knowledge of database programming. High-level components are able to manage all of these database-programming routines.

Example applications using our components

We have had our students make several example-programs using our components(Fig. 5). All of these programs have been made with very little coding. If the students had attempted to produce similar programs without utilizing the componentware design system, it would have required a great deal of effort: they would have needed to write a several-hundred lines of code, including condition- and repetition-program structures, and also would have to study and gain experience in API (Application Program Interface) concepts. Pragmatically, this is an unlikely prospect for any beginner programming-group. Using componentware, they were able to produce their own programs in approximately one week, with most of the students' design time spent on educational content-design.

Discussion

We have developed more than 30 components focused on EFL education, and have made several sample applications using those components (Fig. 3). We have been able to reduce the large amount of development time typically required for producing such applications, as well as reduce the level of knowledge required to create such applications. We do not think however that 30 components are sufficient for producing a large variety of EFL applications. We will need to continue to survey teachers' requests, and develop more components. Additionally, we have to further research each component's "hidden programming-routine size" (the number and "depth" of internal structures determining available features in a component). We can incorporate a large number of features into one component, however it is sometimes hard, particularly for the beginner group, to become skilled in the use of a more complex component, as there tends to be a larger number of parameters to set in a feature-laden component. This fact has shown us that an "all-purpose" tool (with features for every contingency) may sometimes be functionally useless for its target users. On the other hand, if every individual component is too "simple", this creates a situation where a welter of components must be used in order to produce applications; as a result, it becomes difficult to decide which component to select and as well, more coding becomes necessary. Thus, there is a trade-off between the 'simple component' approach versus the 'multi-purpose component' approach, which must be balanced.

Conclusion

We have described a new approach to educational software development. Teachers should be able to accomplish the following goals utilizing a componentware approach:

For both Beginner and Intermediate Groups:

1) To make new applications for the classroom using high-level components.
2) To make new and sophisticated applications for their classrooms mixing high-level-components and basic-components

For Intermediate Groups:

3) To make new types of high-level components and/or applications using basic components, and to provide them to the beginner group.
4) To make new basic components using/improving our components, and to provide them to the beginner group.

As previously mentioned, we have been focusing on EFL education, however we believe our development concept is applicable to numerous educational fields. We have recently begun to develop basic components for mathematics and physics education. The Borland Delphi object-Pascal language is our chosen development environment. Nevertheless, the componentware approach can be executed in other object-oriented language environments.

Developing an Organisational E-Learning Strategy

INTRODUCTION

During the past five years Blackboard and WebCT have become the world's leading learning platform vendors, having achieved spectacular market penetration in a small number of countries. Learning platforms offer enhanced student access to learning materials, straightforward integration of digital content and a range of student interaction and tracking services. Different systems have different emphases, but common features include content authoring tools, calendars, syllabi, discussion boards and assessment mechanisms.

Liverpool John Moores University (JMU) is one of the largest universities in the UK. It is a multi-faculty institution with in excess of 20,000 students. Its first learning strategy, in 1995, sought to identify and make explicit the University's commitment to learning development and to integrate this in the context of other University policies and strategies. The underpinning principles of the strategy were derived from the University's mission statement, with detailed targets for implementation, responsibilities for action and costings. In the years 1995 - 1999 institutional and local structures and processes were developed to support implementation, with a particular strength at the local level being the introduction of Learning and Teaching Coordinators (LTC's) in each of the University's Schools.

CONCISE CASE STUDY

The purpose of the case study is to examine institutional Learning and Teaching Strategy and decision-making which impacts on the promotion of ICT for learning, In Liverpool JMU These particular processes have been monitored by the Higher Education Funding Council for England (HEFCE).

Annual reviews of the JMU learning strategy, since 1995, demonstrated that significant progress was made across a number of fronts. It was observed that a number of real improvements in the learner support infrastructure were made, with substantial investment in development of the University network giving better access to ICT, induction in the use of ICT and in extending opening hours of JMU's three Learning Resource Centres. Increased emphasis was placed on front-loading support for students in the early stages of programmes, with a range of local subject-specific pilots focusing on the development of tutorial modules.

As a result of these initiatives there was evidence of increased use of ICT by both staff and students, particularly in the use of email for communication and there occurred a range of developments across the University in the area of web-based learning.

In 1999 a range of LTA themes, for the following three years, was developed. JMU took, as a primary focus, the need to provide a straightforward and limited set of initiatives that were meaningful to all groups of staff concerned with supporting learning within JMU and their franchised programmes. Five themes for Learning, Teaching and Assessment for the academic years 1999/2002 were developed. The five themes were positioned in two functional categories: three **Learning Themes** that encompassed various fundamental aspects of LTA; and two **Enabling Themes** that underpinned the Learning Themes, infusing and supporting them in a way thought to be fundamental to the success of the whole enterprise. For each of the five themes there was a deliberately planned short period at the outset for evaluating the effectiveness and impact of developments, in order to maximise the effectiveness of the new initiatives. Similarly as each new theme was undertaken, a robust processes for monitoring and evaluation was incorporated.

The five themes were:

- Effective and Efficient Assessment
- Curricular Enhancement for Employability
- Enhanced Learner Support
- Promotion of ICT for Learning
- Staff Development for Learning, Teaching and Assessment

The rationale of the fourth **enabling** theme, Promotion of ICT for Learning, was concerned with exploiting new learning technologies in relevant and appropriate ways in order to enhance learning, teaching and assessment. The theme recognised that the shift towards greater use of ICT in student learning brings with it a requirement for staff to have the requisite skills and understanding in order to exploit the huge potential of ICT in interactive learning. As part of this theme there was a particular focus on:

- Staff development;
- Opportunities for ICT supported Learning
- Learner Support Infrastructure

The stated goals of the theme were:

1. To identify and adopt good skills and practices for ICT-supported learning;

2. To incorporate interactive ICT usage in the learning process throughout JMU;

3. To identify the resource implications of promoting ICT-enhanced learning

A Learning Development Team was created at JMU to focus on the operationalisation of the LTA strategy. This core permanent team is small but LTA Theme Coordinators and part-time secondments for specific projects supplement it. There are five LTA Themes and each of these has a Coordinator working for 50% of their time on activities relating to the implementation of the LTA strategy. The Theme Coordinators function within the Learning Development Team but spend much of their time working across the University. They report their activities to a Learning Innovation Committee.

As mentioned previously there had occurred a range of developments across the University in the area of web-based learning. These began in 1997 with the introduction of a staff/student resource, a university supported Document Management System to support academic staff in placing materials on its campus wide information system (cwis). This web-based system supported small pockets of Learning and Teaching activity. In 1998 a number of staff, from several Schools within JMU, designed and developed complementary templates to serve the needs of students for modules of different programmes. The two separate web-based support mechanisms operated in parallel within JMU. In one case, Liverpool Business School academic designed templates formed the basis of the principal module web support provision for students. The latter initiative supported the stated goals of the fourth stated LTA theme for JMU and many research studies were undertaken concerning student perceptions and the impacts of the web-sites on learning and teaching development.

In 2001 a Web-Supported Learning Working Group was established at JMU to identify, evaluate and approve systems that support on-line learning. The group consisted of academics from a range of faculties, educational researchers, web-site developers, Learning and Information managers, Computer and Information Managers, Learning Development Team managers and it was chaired by the university's Director of Academic Innovation. As a consequence the group evaluated commercial Virtual Learning Environments (VLEs). Such as Blackboard and WebCT with some being tested by a number of different Schools and Service Teams. Other platforms were also investigated. The 'approved' system, Blackboard, was identified on the basis of comments and experiences from representatives of all stakeholders.

Scenario planning was undertaken, determining the functionality required to provide the ideal platform for JMU, including a JMU portal. Criteria included: capacity for all academic staff to have their own online space; training for academic staff; student allocation of modules and modular catalogue details; common service for on and off campus students; processes for faculty to manage and develop learning materials; and seamless integration with existing (and those in development) information technology systems.

The beginning of the 2001/2002 Academic Year saw the arrival of the **Blackboard Virtual Learning Environment** at JMU, replacing the JMU supported Document Management System as a web based system to support learning and teaching. The introduction of this VLE also provided a viable replacement for the academic designed templates. As well as allowing access to course materials via the web, Blackboard also offers a number of communications tools, including Announcements and the Virtual Classroom, all of which can be used to enhance the learning experience.

The Web-Supported Learning Working Group has now evolved into a Web-supported Learning Panel with representation from across the university, the panel is tasked with addressing issues concerned with Web-supported Learning; strategy, evaluation and projects. It is now the case that previous research and current research studies concerning student perceptions and the impacts of the web-sites on learning and teaching development will be focused on establishing 'best practice' in the internal use of VLE's.

In an effort to further enhance and develop initiatives for the five themes for Learning, Teaching and Assessment during the 2001/2 academic year over thirty-six awards were given out by the Learning Development Team to celebrate excellent practice in learning, teaching and assessment.

Awards were made using £63,000 of the HEFCE learning and teaching strategy money to make these awards in four categories. They involved staff from every School/Faculty and from Learning and Information Services and included teaching and learning, technical, administrative support staff and postgraduate students. Many of the awards were team awards. The aim of the awards was to raise the profile of teaching and learning at JMU and to recognise and reward effective practice."

The four award categories were: Curriculum Innovation: to recognise innovative curriculum development work that has already been undertaken Curriculum Development: to support new curriculum development work Teaching-related Research: to support staff researching their own learning, teaching and assessment practice Teaching Fellowship: to recognise individual excellence in teaching.

Many of the awards in Curriculum Innovation and Teaching-related Research support the Promotion of ICT for Learning theme and one of the three Teaching Fellowships is specifically focused on gauging and disseminating 'best practice' in the use of Blackboard.

Only one learning platform is now supported centrally at JMU. Academic staffs in Faculties are free to use other platforms but must fund and support them themselves. Whilst JMU has selected a single centrally supported learning platform, the University recognises that this is a rapidly evolving market and will regularly review its approach, and has put in place strategies to facilitate platform portability.

SOME RESEARCH FINDINGS CONCERNING BLACKBOARD USE

A series of surveys were undertaken on students using web templates for modules designed by academics in the academic year 2000/2001. The cohorts studied were both undergraduates and postgraduates. The surveys explored student attitudes and perceptions to the web-sites as well as providing insights into learning strategies adopted. Knowledge of student Learning Styles was incorporated into all assessments made. Results from these surveys have been reported (McClelland 2001a & 2001b). Follow up surveys of undergraduate and postgraduate students on modules using Blackboard (where the previous supports were web templates designed by academics) has also been undertaken (McClelland 2002 unpublished). .

A series of studies concerned with the sum-total of technology-based supports currently offered to students in JMU has been undertaken, representing a UK university that has a technological infrastructure (McClelland, 2001c). The research that supports this publication examines student perceptions of administrative support systems offered through a campus wide information system and range of supporting web-sites hosted at JMU. The research gives a systemic perspective and refers to Blackboard (now JMU's chosen format for web-site presentation to students).

In order to obtain vital feedback on the new Blackboard system, two JMU surveys were implemented in December 2001 to obtain user feedback of the system - one survey for staff, the second for students (Bird and Connor, 2002 unpublished).

A summary of the findings for the above surveys can be found in Table 1

It can be seen from conclusions in Table 1 that there is overwhelming support for E-Learning in Higher Education being an evolutionary change rather than revolutionary. Internal research (from JMU) indicates and supports incremental changes and this is mirrored by experiences in a comparable University to JMU, Edith Cowan University, Australia (The Observatory on borderless Higher Education, 2002).

Research Findings	Conclusions
Academic designed web-site supports enable flexibility for both students and tutors, avoiding restrictions such as time, place and accessibility of knowledge supports. Students at lower levels of a programme use sites more frequently. (McClelland, 2001a & 2001b).	Restrictions such as time, place and accessibility of knowledge supports support a continuous change model. Usage patterns indicate increasing usage of web-sites for less experienced learners.
Introduction of a commercial VLE, Blackboard, shows no major differences in student perceptions of quality, content, administration and learning experience than those experiences of academic designed web-sites. No differences in mean importance of all Blackboard site supports were observed when factored by the variable Student Learning Styles. Previous research on none Blackboard web-sites (McClelland, 2001b) had found one variance from this with External Links (exploring the web).	The no differences observation infers continuous change from a simple to a more complex form. The Learning Styles observation infers that Blackboard does not discriminate preferred learning styles of students and supports. This is a step improvement from observations on web-sites designed by academics. This can be viewed as continuous change.
At JMU the principles of clarity; attention; integrity and strategic use of informal information have been used in it's strategic transformational change processes due to a combination of consistent information flows; a series of targeted internal studies; a focus of all communications supporting organisational objectives and through the transparency of the transformation process, and wide involvement of staff, strategic use has been made of informal information. (McClelland, 2000 & 2001c)	Action and communication are developmental rather than major changes. The communication within JMU is to effect change and influence action in the direction of JMU's overall interest.
Almost 1000 students responded to a survey of Blackboard use (n = 900), 50% stated that all or most of their module leaders employed use of Blackboard. 71% indicated that they would like it used for more of their modules. There is evidence that Blackboard has a role to play in widening participation. Majority of staff and students view Blackboard as having great potential in enhancing and supporting learning but acknowledge that it needs to be exploited much more (Bird & Connor, 2002)	Uptake is gradual in the transition from JMU supported and academic designed web-provision, but greater than that previously experienced. There is a wider acceptance and greater perceived benefits. Awareness is widened and initiatives are developing. The changes are developmental and not fundamental complete changes.
In a case study on Edith Cowan University's introduction of Blackboard (Australia) the lessons that were taken on board were 'establishing a clear relationship between institutional strategy for online learning and the platform selection process; mapping the necessary links between the platform and existing in-house information technology and the value of active engagement and support for one learning platform, whilst other systems were allowed where local markets dictated.' The Observatory On borderless Higher Education, 2002).	Supports JMU experience of internal monitoring, evaluation and consultation processes, but focusing and supporting one platform whilst allowing flexibility. Supports incremental changes.

Table 1 Research Findings and Conclusions Concerning Blackboard Use to Date.

COMMERCIAL DEVELOPMENTS ASSOCIATED WITH BLACKBOARD

Liverpool JMU is currently developing a generic intellectual property policy for teaching and learning resources, including online materials available through the Blackboard sites, on-line articles and e-Book arrangements with publishers such as McGraw-Hill.

As a result of the experience gained through developments of web-sites and online delivery, JMU is part of a consortium producing and facilitating a Masters in Enterprise (M.Ent.) degree for Small to Medium size Enterprises in the UK. This is a distance programme utilising a Blackboard platform.

Liverpool Business School, in the JMU Faculty of Business and Law has developed a suite of Masters level modules on Blackboard which can constitute tailored Masters Programmes such as Masters in Business Studies (MBS), Masters in Business

Administration (MBA). These will allow more flexibility in differing delivery modes and a commercial product for international educational markets.

CONCLUSION

Research at JMU has demonstrated that web-sites enable a more consistent corporate image on-line, allow support services to focus and raises faculty and student skill levels and reduce confusion between the functionality of different systems. Use of the commercial VLE, Blackboard, offers to facilitate integration with in-house systems, such as Oracle.

The JMU experience holds a number of lessons, including establishing a clear relationship between institutional strategy for online learning and the learning platform selection process; mapping the necessary links between the platform and existing in-house information technology and the value of active engagement; support from senior managers; celebrate excellent practice in learning, teaching and assessment by motivating staff to develop sites by providing suitable reward structures; channelling best practice and supporting staff development in producing appropriate resources.

Although it may be too early to comment on to what extent, and in what ways, VLE's will have a long-term effect on teaching and learning a noteworthy development are the immediate commercial possibilities and educational markets for Programmes endorsed by universities and mediated through commercial VLE's.

Evidence of the Need to Support the Development of On-line Collaborative Skills: An Action Research Study

Laura April McEwen, Department of Education, Concordia University, Canada, laura@education.concordia.ca

Jennifer Sclater, Department of Education, Concordia University, Canada,
jennifer.sclater@education.concordia.ca

Abstract: This study examined the relationship between the quality of intra-group on-line collaboration among groups of undergraduate learners on the quality of products produced. The quality of on-line collaboration was assessed by the instructor and Teaching Assistant with the CSCL process assessment tool. The evolution of quality of intra-group on-line collaboration was examined over time, as was the quality of group products for the first and third on-line activity. Findings suggest that the quality of collaboration significantly impacted the quality of products produced by a group. The results of this study underline the need to provide support for the development of learners' on-line collaborative skills prior to the introduction of learning activities where grades are contingent upon effective collaboration. The strategy of self and peer assessment practices is introduced as a potential means of fostering the development of important collaborative skills essential to learners' successful negotiation of this novel learning arrangement.

Introduction

Educators are being encouraged to move away from directed instructional approaches and adopt a more interactive style of teaching. This fundamental shift in educator orientation involves dramatic adjustments in the flow of communication. Within such a context, learners are encouraged to interact among each other as well as with educators. One method of promoting interaction among students is to include collaborative projects in the instructional design of courses. In keeping with the current emphasis in academic institutions on social-constructivist theoretical orientations the incorporation of these learning strategies have been on the rise (Bagley & Hunter, 1992; Hansen & Perry, 1993; Morris & Hayes, 1997).

The emergence of technological tools such as computer mediated communication (CMC) software presents the potential to facilitate collaborative interaction at a distance (Keegan, 1993; Hiltz, 1994; Garrison, 1997). CMC is a specific type of human interaction that enables individuals to exchange knowledge, thoughts and feelings via technology. The culmination of this marriage of theory and technology is a powerful, dynamic learning environment unconstrained by time and space (Garrison, 1997; Hiltz, 1994; Keegan, 1993). Few would argue the compelling potential of such an active learning context, but along with this powerful pedagogical redirection come many challenges for learners.

Computer Supported Collaborative Learning

Computer supported collaborative learning (CSCL) environments are the product of constructivist approaches to learning supported by the technology of CMC software (Wenger, Holloway & Garton, 1999). CSCL can be defined as the educational use of computer technology to facilitate group learning. The CSCL process is best conceptualized as a dynamic interrelationship between several key elements which require learners to: (a) define learning goals, (b) make individual contributions to the group process, (c) negotiate roles and responsibilities, and (d) synthesize individual contribution into a cohesive group product. This interrelationship can provide learners the opportunity to build knowledge collectively (Brandon & Hollingshead, 1999; Dehler, 1998; DeSanctis & Monge, 1998; Garrison, 1997; Hiltz, 1994). However, an underlying assumption of such learning arrangements is that learners possess the skills to effectively collaborate within the on-line environment.

Central to the concept of collective knowledge building is the ability of learners to *communicate effectively* or make the implicit, explicit. Research findings suggest that the ability to clearly, concisely, and completely represent individual understanding to others is a skill associated with high ability learners (Linn, & Burbules, 1993). Therefore, we as educators cannot assume that all learners possess this capacity.

Along with learners' individual communication competencies, the characteristics of the medium must also be considered. Perhaps the most formidable task of communicating in this setting is the mastery of the distinct form of communication that this environment demands. In effect communication in the virtual realm requires the blending of skills of reading and interpretation, writing and speech to produce a new form of human interaction.

Most educators suggest building CMC skills gradually (Berge & Collins 1995; Harasim 1996; Hiltz 1994; Misancuk 1997). In this way participants are afforded the opportunity to familiarize themselves with the technology and acquire the skill set which will enable them to communicate effectively through the medium. However, many of the strategies commonly recommended, such as dyadic partnering of learners or the placement of learners in small groups for informal electronic exchange, do not promote the development of on-line collaborative skills.

When the collaborative process is considered, aspects of group dynamics figure prominently. Unfortunately, most learners' prior educational experience has been in the objectivist tradition of instruction, where competition among learners has been strongly promoted (Shepard, 2000; Wiggins, 1993; Wilbrinks, 1997). As learners are often inexperienced with collaborative learning arrangements, generally, their knowledge about critical aspects of productive group functioning may also be lacking.

Ultimately, CSCL arrangements demand that learners synthesize individual contributions to achieve a quality group product. Yet according to Bloom's Taxonomy (1956), synthesizing at the individual level is considered a complex cognitive task. The challenge of this type of task is compounded within a CSCL learning context, as group members struggle to synthesize individual expertise in such a way that all members of the group are richer for the interaction.

Considered in unison, the challenges associated with a collaborative learning arrangement situated in an on-line learning environment are substantial. If learners' grades are contingent upon the quality of a collaboratively produced product, then methods of promoting the development of learners' on-line collaborative skills need to be considered.

The Focus of Assessment

Educators communicate to learners what content and skills are important to learn through the focus of assessment (Boud, et al., 1999). In a social-constructivist learning context effective communication is a required skill, learners' success ultimately hinges upon their ability to communicate their ideas and comprehend those of their peers. Since the purpose of assessment is to promote student learning, assessment practices need to acknowledge the importance of the communication processes and provided incentives and guidance to improve these collaborative skills (Murray, 1999).

Assessment Practices as a Means of Promoting the Development of Collaborative Skills

Proponents of constructivist pedagogy emphasize the need for assessment to become an integrated component of the learning experience (Boud, et al., 1999; Duffy & Cunningham 1996a; Shepard, 2000; Sullivan & Hall, 1997; Wiggins, 1993). Within this framework, assessment is not an end in and of itself, but instead regarded as a tool for promoting individual growth through the development of important metacognitive, critical thinking and communication skills (Frederiksen & Collins, 1998; Linn & Burbules, 1993; Stefani 1998). From a constructivist perspective, successful learners need to effectively self-monitor, evaluate and interact. By including these processes in the focus of assessment, learners are provided with feedback they can use to inform their future performance.

The Study

The current study examined the relationship between the quality of intra-group collaboration and the quality of products produced. Learners were randomly assigned to four-member collaborative group at the beginning of the semester. They worked collaboratively on three group projects over a two-month period. Group membership was stable for the entire course.

Learners' collaborative process was assessed using a tool developed within the research context. Learners received a grade for their individual contribution to the group product based on the five CSCL process assessment criteria. Group products were assessed based on predetermined assessment rubrics.

Methods

Research Context

Technology for Educational Change (EDUC 305DE) is a one-semester undergraduate course offered at a distance by the Department of Education at Concordia University through FirstClass®, a client or web-based computer conferencing system. This course is intended for pre-service teachers, and other interested students from the Faculty of Arts and Science, as an introduction to the possibilities afforded them through the integration of technology into the classroom. Forty-five percent of learners' final grades were derived form three CSCL activities. Each CSCL activity was worth fifteen percent of learners' final grades. A description of the three CSCL activities follows:

Activity 1: Structured Debate

This activity was intended to familiarize learners with the strengths and weakness of CMC. Groups of learners were paired and each group within the pair group was designated an opposing position, presenting either the strengths or weakness of CMC. A reference to an on-line journal was provided in the FirstClass® course conference. Individual learners were asked to select and read an article. Groups were then given a week to collaboratively prepare a position paper supporting their argument with the literature they had reviewed and submit the paper to their partner group for rebuttal. Only the rebuttal paper was graded.

Activity 2: Experience to Practice

This activity was designed to introduce students to the constructivist theoretical perspective by requiring them to build on individual experiential knowledge of directed instructional approaches to learning and collectively convert one of the group's individual contributions to a constructivist learning activity. Learners had two weeks to complete this assignment.

Activity 3:Design

Learners were asked to debate the pros and cons of computer use in the classroom. They were then required to design a classroom activity that incorporated the use of computers. They were asked to define the role of the teacher, indicate the educational level of the students and describe the implementation as well as how it would be assessed.

Participants

Of the 56 learners enrolled in the *Technology for Educational Change* course in the Fall 2000 semester, 52 learners completed all course requirements, 21 learners were included in this analysis. This represented a 40% participation rate. Of the 21 participants in the study, nine were education or Art Education students, 3 were from the faculty of Commerce, three were Sociology majors, 4 were Psychology majors and two were independent students. Eleven females and ten males chose to participate in the study. According to responses to background questionnaires and information gathered over the course of the semester, participants had no prior experience in CSCL. However, students did appear to be familiar with collaborative learning in a face to face context, with 17 of the 21 participants reporting having encountered this form of instructional strategy more than three times over the course of their academic career. Half of those reported having engaged in collaborative learning activities more than ten times.

Instruments

The CSCL process assessment tool was developed in the first cycle of this action research study. It identified five assessment criteria associated with the characteristics of effective on-line collaboration and provided operational definition of each. Table 1: The CSCL Process Assessment Tool presented below was adapted from McEwen (2002). The CSCL Process Assessment criteria appear in the top row of the table. The operational definitions of each criterion are listed in the column beneath each.

Table 1: The CSCL Process Assessment Tool

Criteria	**Distributed Expertise**	**Leadership**	**Provides or asks for clarification/ feedback**	**Clarity and Accuracy of information Provided**	**Quality of individual contribution**
Operational definitions	shared prior knowledge or experience introduced new information, relating it to activity/discussion	initiate discussion of task/group meetings proposes deadlines defines roles posts early offers guidelines to support/ promote group interaction combines/edits group product	provides clarification on task instructions provides constructive feedback on teammate's contribution provides constructive feedback on combine group product provides information/instructions about functionality of software. requests feedback from group on combine group product asks for clarification about group member's contribution	clear concise instructions accurate information or directions	Individual component of task (article summary, personal learning experience) completeness, clarity, and utility of Introduction/ conclusion/section of assignment

Procedures

All FirstClass® messages posted by learners in their group sub-conferences, or Forums, as they became known, for each of the on-line activities were reviewed. The CSCL process assessment tool was used to evaluate the quality of intra-group collaboration. Each learner was assigned an *Instructor Assessed Individual Contribution* (IAIC*)* score out of five. The Instructor of the course assigned the IAIC scores for Activity 1: *Structured Debate*. The Teaching Assistant assigned the IAIC scores for Activity 2: *Experience to Practice* and Activity 3: *Design*. The instructor graded group products according to the pre-determined assessment rubrics.

Analysis

Two analyses were conducted. Given the similarity of task demand for Activity 1:*Structured Debate* and Activity 3: *Design*, a comparison of Group Product quality across these two on-line activities was made. A t-test was calculated on these two samples of scores. An analysis of variance was conducted to compare mean IAIC scores over time.

The Group Product scores for eleven groups for both on-line activities are presented in Table 2. The first column of the table indicates the name of the group. The second column provides the Group Product scores attained by each group for on-line Activities 1: Structured Debate. Group Product scores for Activity 3: Design appear in the third column of the table. The descriptives of Group Product scores are presented in the final rows of the table.

IAIC scores for Activity 1: Structured Debate, Activity 2: Experience to Practice, and Activity 3: *Design* are presented in Table 3. Learners are identified in the first column of the table. IAIC scores appear in the following three columns respectively. The final rows of the table indicate the means and standard deviations for each sample of scores.

Table 2: Group Product Scores for Activity 1: *Structured Debate* and Activity 3:*Design*

Group	**Group Product Scores Activity 1: *Structured Debate***	**Group Product Score Activity 3: *Design***
1	75	93
2	92	77
3	58	93
4	92	100
5	58	87
6	63	87
8	75	87
9	67	93
10	54	77
11	38	97
12	58	93
Mean	66.36	89.45
SD	16.26	7.39

Results

The quality of Group Products improved significantly from Activity 1: *Structured Debate* to Activity 3: *Design* ($M = 66.36$, $SD = 16.36$) to Activity 3: *Design* ($M = 89.45$, $SD = 7.39$). All but one group scored remarkably higher in the final group product. A *t*-test revealed that Group Products scores were statistically significantly higher for Activity 3: *Design*, $t\,(13) = 4.03, p < .01$. A possible explanation is the improved collaboration within groups as represented in improvement in IAIC scores across tasks.

According to mean IAIC scores learners' collaborative performance improved significantly over time. There was a steady rise of the means of the IAIC scores over time, $M = 2.81$, $SD = .98$; $M = 3.64$, $SD = .59$ and $M = 4.75$, $SD = .48$, respectively. The CSCL process assessment tool does appear to have captured improvements in learners' collaborative performance across tasks. An analysis of variance revealed statistically significant differences among the three means of the IAIC scores, $F(2,60) = 31.62$, $p < .01$. This finding suggests a degree of stability both in the improvement in learners' collaborative skills and in the CSCL process assessment tool.

Table 3: IAIC Scores for On-line Activities

Learner	**IAIC Scores for Activity 1: *Structured Debate***	**IAIC Scores for Activity 2: *Experience to Practice***	**IAIC Scores for Activity 3: *Design***

Means	2.81	3.64	4.57
SD	.98	.59	.48

Discussion

The Inter-relatedness of the Quality of Process and Product

There appears to be a definite positive relationship between the quality of process engaged in by groups and the quality of products produced. The stunning improvement in the quality of Group Products from Activity1: *Structured Debate* to Activity 3:*Design*, as shown by the increased grades on the final group products, coupled with the tremendous improvement in collaborative performance as represented in the rise of IAIC scores between activities supports this hypothesis.

This finding raises the important issue of the need to support the development of learners' collaborative skills early on. Apparently, a learning context characterized by a collaborative learning orientation within an on-line environment posed unfair challenges for learners. Upon reflection, we feel strongly that self and peer assessment practices offer educators a means of providing the support learners may require. We suggest that if these practices are appropriately orchestrated within a learner-centered context, learners can be successfully supported through this adaptation phase. These practices can draw learners' attention to the types of activities that promote effective collaboration. Furthermore, as the assessment process unfolds learners stand to further benefit through the development of evaluative and self-monitoring skills.

Conclusion

The findings of this study suggest it is unrealistic to expect learners to suddenly adopt a collaborative learning orientation without supporting the development of social skills necessary for their success. Learners need to understand what constitutes effective collaborative interaction within an unfamiliar learning environment. Self and peer assessment practices offer educators a means of supporting learners' emergent understanding of this learning orientation and the manner in which it is expressed on-line.

A central tenant of the self and peer assessment literature is learners' ownership of the assessment process. According to researchers exploring self and peer assessment practices in on-site learning contexts, feeling of ownership grow out of the act of learners having a hand in either the creation or definition of assessment criteria (Dochy et al, 1999;Topping, 1998). Activities such as these are also believed to foster deeper understanding for learners (Falchikov, 1993; Stefani, 1998). Therefore, truly supporting the development of collaborative skills would require that learners be included in the negotiation of the meaning of the characteristics of effective collaborative interaction. The impact of which could very well be the expression of this knowledge in learners' on-line practice. Consequently, the strength of the CSCL process assessment tool lies in the directing of learners' attention to important characteristics of effective collaborative interaction.

ABSTRACT

It is important to build a community of learners, so that co-operative learning takes place. This is more difficult to accomplish online, where the lecturer has to overcome the natural reticence of students to post in shared class spaces.

This paper suggests constructive methods of ensuring the success of an online course. These include reinforcing and recycling course content in a variety of integrated media, and encouraging students to become leaders and help their classmates.

We report results (from 1999-2001) from three undergraduate and two postgraduate computing courses that each have a significant proportion of the course taught online. These courses are studied by students with a wide range of ages, ethnic backgrounds, life and work experiences. We report widely ranging student participation rates in a variety of online discussions and course exercises, and discuss the contributing factors that cause some branches of the online learning tree to blossom and others to wither.

1. INTRODUCTION

Many researchers point out the importance of building a community of learners, (Campbell and Hawksworth, 1999, Foley and Schuck, 1998, Lehtinen, et al., 1999 , McSporran and King 2002), so that students can learn from each other. Felder and Brent, (1994) cite research that shows that "cooperatively taught students tend to exhibit higher academic achievement, ... better high-level reasoning and critical thinking skills, deeper understanding of learned material, more on-task and less disruptive behavior in class, ... ".

Online conferences, either synchronous or asynchronous, are generally recognised as a powerful tool for active learning. As Klemm (1998) points out, they require students to "comprehend what is being discussed by others, to create ideas in the context of the topic at hand, to organize thinking coherently, and to express that thinking with carefully constructed language (hopefully, clearly and concisely)". However it is also generally recognised that students are reticent about posting in shared class spaces – perhaps because they lack the confidence to assert themselves in public, or they are afraid of embarrassing themselves in front of their peers. Klemm (1998) recommends eight ways to increase quantity and quality of student participation in online conferences.

It is all too easy to invite student participation in an online course only to find that the contributions never happen. It is necessary to encourage and cajole students to participate using inclusive, enthusiastic and motivational language. However this is very time-consuming, and can result in the tutor feeling trapped in a "virtual prison" (Hart and Gilding, 1997). In this paper we share our tips and experiences for ensuring student participation, while reducing personal time overheads for tutors.

Some of the pedagogical strategies that we employ to ensure the cognitive engagement of the online community include:

- Encouraging student leaders
- Forming student groups

- Peer grading or comment and student exemplars
- Motivational, student-centered, socially inclusive, enthusiastic, positive, and conversational dialogue in a variety of media, such as email, discussion forum posts, time-specific course website announcements and co-ordinated tasks.

2. ABOUT THE COURSES

We discuss three courses in the Bachelor of Computing Systems degree (Internet and Web Development 1 and 2, and Help Desk) and two courses in the Masters of Computing degree (Internet Applications and Website Management). All our courses are taught in flexible task-orientated manner. We generally offer co-ordinated classroom sessions, paper and online lecture notes, practical exercises, and integrated usage of communication alternatives offered by the standard tools included in the course website building shells, Blackboard CourseInfo and WebCT. All of the courses involve some degree of assessment that is conducted online.

Internet and Web Development 1 is a popular introductory course, described in previous research (McSporran and Young 2001, Young, et al. 1999). In the first assignment (20% of total) the students research an aspect of the Internet in groups. Part of this assignment (20% of total) is attributed to online communication: how effectively the students communicate using email, web-based discussion forums and chat.

We first implemented a web-based discussion forum in IWD1 in the 1999-2000 Summer School, which was the first real remote class. The discussion forum was promoted, but we were disappointed with the low student usage, even though the remote students had few other ways of forming a community of learners, (Dewstow, et al. 2000).

In Semester 1, 2000 we assessed student usage of the group discussion forum for first time, forcing students to use it. To our surprise we noted that usage didn't improve, and with hindsight we noted that usage of the discussion forum in the first Summer School was actually quite good.

In 2000, the Master of Computing degree started at UNITEC. This is taught part-time one weekend a month, with online activities between the monthly class sessions. After experiencing the low usage of the IWD1 discussion forum, the decision was made to follow the advice of Klemm (1998) to increase quantity and quality of student participation. We designed structured and/or assessed exercises to encourage discussion forum usage, described in detail in a previous paper (Young, 2001).

In Semester 2, 2001, IWD2, a course focussing on real-world tasks and involving many class exercises, was offered for the first time. Very low participation rates in the class exercises were experienced. The decision was made to force participation in Semester 1, 2002, by allocating a proportion (20%) of the first assignment (25% of the course total) for participation in 20 class exercises. There was a dramatic positive effect on participation rates.

3. DESCRIPTIONS OF EXERCISES UTILISING DISCUSSION FORA

Examples of structured, assessed exercises that utilised a discussion forum include:

- **Website critique**
  An individual component of a postgraduate course group research project. Three member syndicates choose a topic and each student submits a critique of a single website within the top ic area. A week later the students are required to reply to their syndicate members' critiques. After a further week the writer of the critique submits a response that integrates all the posts. Thus in a three person group, each student writes two replies, and each student receives two replies.

- **Debate**
  A postgraduate course syndicate assessment that followed a typical debate format, again on a weekly basis, with the groups required to make opening and closing statements and to respond to the points made by the opposing syndicate.

BEST COPY AVAILABLE

- **URL Synopsis**
  An individual assessment, designed to encourage the postgraduate course students to continue their reading around the subject and develop their communication skills. They were required to write one sentence reviews of a useful web resource. These were marked on quality and applicability of the resource and accuracy of the review.

Some examples of structured, yet non-assessed exercises that utilised the discussion forum include:

- **Website changes**
  The students in this postgraduate course were given a case study for a complex e-commerce website, which included many screenshots of the different pages of the website. The students were asked to read the case study, to visit the website, and to identify the many changes that had been made since the case study was written. They were asked to list changes, giving reasons why they thought the changes were made, in a post to the discussion forum. After one week there were no posts to the discussion forum. The lecturer then posted a list of 5 changes and asked the students to reply with reasons, which only solicited 2 reply posts.

- **Server monitoring**
  Undergraduate and postgraduate students were asked to repeatedly test the response time of various websites, to calculate the average response time and to post their results to the discussion forum for collation. In classes where this exercise was not assessed there was poor participation. In IWD2, Semester 1, 2002 where participation was assessed, rates of close to 100% were experienced.

4. STUDY METHODOLOGY

Data was collected from course website usage statistics. WebCT supplies data on the number of discussion forum postings read and posted by each student, although there is no way to identify assignment group posts or general posts. Blackboard offers no data for each student, necessitating a manual count of student postings. It is impossible to detect how many posts each student read.

In this and our other studies we have decide to include a student's records if those students have recorded at least one assessment mark. Some of the students who drop out without submitting an assessment utilise the course website fully, while some students who submit one or more assignments never visit the website.

5. STUDENT DISCUSSION FORUM PARTICIPATION RESULTS

[Table 5.1: Average student discussion forum participation, IWD1.]

Semester	Average Posts Read	Average Posts Made
Summer School, 99-00	75.0	4.0
Semester 1, 2000	21.5	3.0
Semester 2, 2000	23.1	3.1
Summer School, 00-01	16.9	3.5
Semester 1, 2001	32.0	3.3
Semester 2, 2001	30.6	5.3

Table 5.1 reports participation in the IWD1 discussion forum, 1999-2001. The average number of posts read, and posts made by each student are reported - generally participation rates are low. The 99-00 Summer School has a high Average Posts Read result proving that this cohort of students developed an online community of learners - they really were interested in what the other students had to say.

In contrast, the figures for the 00-01 Summer School are very low. Two reasons for this may be:

- This cohort was mainly composed of Asian students who preferred to form their learning teams offline. Felder and Brent (1994) note that co-operative learning can occur in or out of class.
- The lecturer teaching this online course was disadvantaged by personal injury and made far less posts than normal.

Having experienced low participation rates in 2000, we increased our efforts to promote the discussion forum and there was improvement in 2001.

Table 5.2 and 5.3 describe different categories of forum activities, based on the work of Klemm (1998).

[Table 5.2: Average discussion forum participation, IWD2, Semester 2, 2001. Numbers in parenthesis are the number of posts that each student **should** have made.]

Forum activity type	Posts Made
non-Structured, non-Assessed	0.6
Structured, non-Assessed	1.6 (4)
Structured, Assessed	3.8 (4)
Total	5.0

[Table 5.3: Average discussion forum participation, postgraduate courses, 2000-2001. Numbers in parenthes is are the number of posts that each student **should** have made.]

	Posts Made			
Forum activity type	S1, 00	S2, 00	S1, 01	S2, 01
non-Structured, non-Assessed	2.6	0.2	1.2	0.1
Structured, non-Assessed	-	0.4 (1)	0.6 (1)	1.2 (2)
Structured, Assessed	7.4 (8)	6.0 (5)	7.7 (8)	6.3 (7)
Total	9.9	6.6	9.5	7.6

Postgraduates would be expected to be more motivated to take part in class discussions than undergraduates. However levels of participation in non-structured, non-assessed discussions were equally poor at both levels. Levels of participation in the General forum (non-structured, non-assessed discussions) in the postgraduate course, 818, were particularly poor, because there was no attempt by the lecturer to promote discussions. Levels of participation in structured, non-assessed exercises were disappointing. Only when the exercises were assessed was there near 100% participation. These results may be because of the non-English speaking background of a large percentage of the postgraduate students.

[Table 5.4: Average discussion forum participation, Help Desk, Semester 2, 2001. Numbers in parenthesis are the number of posts that each student **should** have made.]

Forum	Posts Made
General	0.9
Assignment 1	2.3
Industry Contacts	1.8 (1)
Personal Diary	26.6 (14)
Training Day	2.6

Table 5.4. shows that participation in the Help Desk discussion fora, in Semester 2, 2001 was considerably greater than required, and greater than the other courses. Some reasons for this success may include:

- An important outcome of the course is to improve communication skills.
- Students only receive departmental help with their industry placement if they display the level of communication skills required.
- Students develop personal relationships in class during the first six weeks of the course, which helps foster later online communication. Campbell (1999) found that quality of online contributions on a distance education course improved after the mid-semester class get-together.
- Several of the fora were related to real world tasks and involved peer grading. Klemm (1998) recommends that discussions should be interesting, require a deliverable, and involve peer grading.

6. DISCUSSION

6.1 Discussion Fora

We have noticed a trend for discussion fora to wither and die. There is often an initial flurry of posts as students excitedly discover the system and look for group members; then the numbers of posts falls off through lack of encouragement. It is important for the lecturers to respond quickly to queries posted in the forum, so that students are not discouraged. This sets a precedent and students thereafter except a quick response. On several occasions we have noted that if a question on the discussion forum has not been answered within a few hours, the student will then email us.

To keep the level of activity on a discussion forum ticking over it is necessary to continually post new material. This can be very time-consuming. Campbell (personal communication, 2002) found that student demands for attention became overwhelming and she therefore introduced two non-academics to her course to help respond to basic student enquiries.

We have a two-fold strategy for ensuring that contributing to a discussion forum does not overwhelm us. Firstly we recycle posts from previous semesters. Having built up an electronic resource of discussion forum posts, we can quickly copy and paste into a "new" posting, giving the illusion of a thoughtful posting. In addition, if an important news story occurs we can copy and paste it into the discussion forums for multiple online courses.

Our second strategy is to encourage students to take on a leadership role and respond to other students discussion forum posts. This is discussed in Section 6.3.

6.2 Announcements

We deliver administrative, motivational and content-specific announcements to our students in more than one media: emails, and course website announcements and tasks, believing that strong integration of a variety of learning materials has a beneficial outcome.

We send out weekly newsletter emails to the students on the IWD1 and Help Desk courses. These contain content such as class administration issues, relevant news items, motivational material and notification of changes to the course website. A major component of the emails is content related to the assignments, such as upcoming deadlines, milestones (what should have been accomplished each week) etc. We re-use weekly emails from previous semesters, but with some editing so it is possible to add new material, for example answers to questions that may have been asked in class. The weekly emails are sent out every Friday, which allows the students to revise what they should have accomplished each week, and to prepare for the forthcoming week. They are in a standard format that the students become comfortable with; student comments refer to them as being "well organised".

We utilise standard weekly announcements that are reused every semester and one-off announcements that may come up, for example relevant news stories and questions asked by students.

An example of a weekly announcement from the IWD1 course: "In Week 3 the theory session is on search engines and effective searching while the practical session covers HTML Tables". The same text is re-used in the calendar tool, as a time-limited announcement on the front page of the website, in the weekly email, and in relevant discussion forum posts. An example of a relevant discussion forum post would be: "This week we covered search engines and effective searching in the theory session. You may find it helpful to share your experiences of using search engines with your group."

Blackboard also offers a Tasks tool, which allows students to see what tasks are currently due. Students can order these by priority or due date, and can change priority and toggle their Tasks from "Not Started" to "In Progress" to "Completed". Believing that this is a powerful tool for students to manage their own learning, both authors began to use the Tasks tool in our Blackboard hosted courses in Semester 1, 2002.

6.3 Community Leaders

Kim (2000) discusses the importance of encouraging online community members to become leaders and help other members. The benefits for the leaders are:

- Rewards of being an "insider",
- Satisfaction at helping others,
- Reinforcing their learning by teaching others
- Gaining new skills,
- Receiving feedback about their performance.

Leaders can either be in some official capacity, or simply enthusiastic members of the normal community. Oliver et al., (1997) suggest that "ways to encourage capable students in the class to spend the time to view postings and submit solutions, and tips and tricks" should be integrated into the online environment.

There are a number of ways of encouraging leadership (Kim, 2000). Firstly it is important that the lecturer leads by example, by maintaining a friendly, responsive, collegiate voice on the discussion forum. Next it is important to offer leaders some sort of status or reward, ranging from a simple acronym in their website username to awarding stars for helpful discussion forum posts. Finally, a document explaining the leadership process is created. This document contains information on:

- The process involved in being a leader,
- The personal skills that make a good leader,
- The benefits of becoming a leader,
- Good practice for leaders.

Such a document could be describing an official leadership role, or simply a page on the course website that encourages capable students to help others.

We encourage a leadership process within the IWD1 Assignment 1 groups, by asking the students to designate a group leader to represent the team. This individual receives private emails from the lecturers and is encouraged to help their fellow team members.

In Help Desk the students undertake a project to plan a Training Day. This is a group project, with each group assigned a different part. Each group chose a group leader, and all contact with the lecturer was through the group leaders.

Kim (2000) advocates creating a "backstage" area for leaders to gather, relax, prepare and discuss topics relevant to leadership roles. This private gathering space could be a mailing list, private discussion forum or chat room. In Help Desk a private discussion forum was created for the Training Day group leaders. Independently of the lecturer the group leaders organised a face-to-face meeting of all group leaders, when they discussed whether each group was on track. At the training day debriefing, the leaders commented that the face-to-face meeting was very useful, one student commented that it would have been helpful to appoint a leader of leaders since there was no-one to chair the meeting and act as an overall project manager.

Kim (2000) promotes the use of feedback loops to keep track of leader performance and, if necessary, to intervene. In Help Desk this was accomplished by entries in the student's personal diary, which could be monitored by the lecturer. At the end of the course group leaders commented on the performance of their group, while group members commented on the leaders' group management skills. An additional benefit for the leaders was that the lecturer offered to allow the students to include her name as a referee on their CV.

We also acknowledge student excellence by highlighting the best student work. The best student assignment websites are displayed in an annual gallery, and examples of good work in class exercises are highlighted and acknowledged. This is a driver for encouraging quality student work, and indeed we have noticed a general positive trend in the quality of student websites.

7. CONCLUSIONS

To build a successful community of learners online requires the same teaching skills as building a community in a classroom. Motivating and responding to students online is very time-consuming. In addition the lecturer must practice many different ICT skills. If employing teaching assistants is not an option, then to avoid lecturer burnout it is necessary to save time by recycling content, encouraging student leaders and good time-management.

Content can be redistributed and reinforced in a variety of integrated media such as emails, discussion fora, course notes (both hard and soft copy), exemplars, and in the various tools provided by the course shell such as calendar, announcements and tasks.

Strategies for encouraging student leaders are essential to motivate students to help others online.

We also need strategies to encourage students to ask questions in public fora, such as allowing students to edit or delete their posts, to post anonymously, or to build in opportunities for private communication, such as private group forums.

We hope that other online educators will learn from our experiences, as we learn from others.

8. ACKNOWLEDGMENTS

Our thanks to all the students on our all courses, 1999 to 2002.

Enhancing Web-Based Materials with Video Clips

Susan Mehringer
Cornell Theory Center
Cornell University
Ithaca, NY USA
susan@tc.cornell.edu

Abstract: The Virtual Workshop is a Web-based set of modules used to provide distance education in high-performance computing. One technique we are currently incorporating is the use of video clips. We are working with two types of clips. The first type is screen and audio capture for tool demonstration. The second is using a film clip of a speaker in conjunction with other Web-based materials. This paper describes the video clips, why they are used, how they are incorporated into existing online materials, design issues, and evaluation plans.

Background: CTC and the Virtual Workshop

The Cornell Theory Center (CTC) began offering asynchronous distance learning over the Web in 1995, with its first offering of the Virtual Workshop. To date, we have conducted fifteen Virtual Workshops for over 1000 participants. Participants typically are undergraduate through Principal Investigator in academia, or a researcher or scientist in a corporate or government office. These workshops cover various topics in High-Performance Computing. Each workshop is comprised of about ten modules, delivered over the course of four to eight weeks. Our courses are taken by those seeking professional development in high-performance topics, and those who more specifically want to learn how to use CTC resources. Those who complete a course are awarded a certificate. We initially offered web-based workshops to reach people who could not travel to Ithaca for training, but we now find that many people prefer the medium, progressing at their own speed, and being able to take portions of the course at any hour.

A goal in the Virtual Workshop evolution is experimentation with techniques intended to provide more interaction, as well as options for participants with different learning styles. Features we have added include

- Glossary, written in JavaScript. The definition appears by either hovering the mouse over or clicking on a glossary term.
- Interactive quizzes, written in VBScript. The quizzes are multiple choice forms. Submitting the quiz form automatically grades the quiz and returns a list of questions that were answered incorrectly, with optional explanations. The results are also written to a database, enabling us to review results for problem concepts.
- Personalized detail level with JavaScript. Easily moving between an outline version and a detailed version of the materials allow workshop participants to move through a topic in a way that best suits their learning style and needs.
- Animations using flash, QuickTime. Animations enhance the text description of a concept and break up pure reading material.
- MOO/Chat/ - Discussion Forums. We have experimented with various forums to provide consulting, as well as to promote discussion among the participants.
- Virtual Workshop Companion, utilizing Java programs and Perl scripts. Provides the ability to edit, compile, set run-time parameters such as number of processors, and submit a program, all without leaving the Web browser, via secure authentication.

One of the features we have used for about five years is the addition of video clips. Video clips are most often used to enhance a portion of a topic rather than provide a full presentation, e.g. the majority of a module is text, with a video included to introduce the topic or explain an important or difficult concept. The clips most often contain a speaker, screen capture, or motion graphics.

Unfortunately, using video clips has had a number of drawbacks: a few years ago, even short clips were very large, and could rarely be downloaded over most participants' network connections, and players were not available across all platforms. In development, it was time consuming and difficult to pair video clips with supporting materials, such as Web pages or slides. Network and desktop improvements have largely solved the first two problems, and we began to investigate solving the third.

Finding the Right Tool: Develop or Purchase?

The features we most wanted when playing the clip were:

- The ability to present audio, video, and a Web page or slide together on the Web page
- Synchronization of Web pages with video and/or audio
- The ability to focus attention on different parts of the Web page or slide at specified points during the clip. This would be used sparingly to focus attention, not to the point of annoyance.
- The ability to easily use the controls to stop, start, pause, resume, forward, and rewind the clip. At the same time, total length and current progression through the clip should always be visible. With these features, there is no need for slow motion. If the viewer doesn't understand or misses something, they can simply rewind and replay.
- The inclusion of a table of contents or index, which will allow the viewer to either jump into the desired section directly, or to view the whole segment in one piece.

We began the task of writing scripts to create such a presentation scheme. However, this past November, a new tool became available that meets all of our requirements for video clip creation and display: Microsoft® Producer for PowerPoint® 2002. In addition, this tool allows us to easily add audio, video, and screen capture paired with PowerPoint or HTML pages.. These capabilities were feasible to develop, but using this tool makes it much more cost-effective. Therefore we are now able to add video clips to Web pages where it makes most sense.

Description of the Video Clips

We are designing and producing a variety of video clips. The video clips will be used to enhance existing online materials, and will occasionally provide full lectures. The video clips are intended to improve our online educational materials by making the content more engaging and easier to understand. Two types of video enhancement we've been working with for several years now are speaker video or audio only, and screen capture.

Some web design sources, such as (Horton 2000) recommend video be used only as a last resort, for several well-founded reasons, including bandwidth requirements and production expense. This source and feedback received to date firm our preference for including short clips, only where most needed.

Screen Capture Video Clip

Capturing a computer screen session is a common feature in tools such as SnagIt from TechSmith®. Most file types created using these tools can be incorporated into Microsoft Producer projects, or Microsoft Producer itself can be used to capture the screen session.

Using screen capture with narration, we can record the technical expert "showing" how to use a tool or program, and hear him/her explain the process. In other words, this is a screen recording, with a speaker voice-over. Ideally, it has the effect of looking over the expert's shoulder while a tool or procedure is demonstrated and explained. Previously, our online materials covering use of graphical tools would use text and screen stills followed by a tutorial that walked the reader through the steps of a simple use of the tool. This is very tedious, error-prone, and frustrating. We feel that screen capture is a faster, more effective introduction.

Currently, our display for screen capture video clips consists of

- A video area, which should be as large as needed to see the detail of the tool being demonstrated
- An audio recording

- A table of contents, which can be omitted if the clip is very short, or the procedure cannot be broken into distinct sections
- A small HTML section which contains typical Web page information, such as date, copyright, and a link to return to the home page

Additional design possibilities we are experimenting with include:

- Offering the option to try to use the tool while viewing the demonstration.
- Using annotation such as a red circle or arrow to bring attention to portions of the screen.
- Including a set of several clips to cover different scenarios and programming languages.
- Making available supporting material, such as relevant hyperlinks.

Speaker Video Clip

Using speaker video paired with a Web page, the speaker video can assist in explaining a difficult point or be utilized to give a full talk. A speaker video can be helpful in giving the materials a human look and feel. Most of the people who use our materials never see the developers and consultants; many have never seen Ithaca. Adding a "Welcome to the Virtual Workshop" clip or a clip that introduces Virtual Workshop participants to the consultants serves to put a face on the materials, and hopefully, make them more comfortable interacting with us by email or chat room. As we all know, individuals do not all process information the same way; some learn better by reading, some by watching, some by experimenting, and of course sometimes a difficult concept only becomes clear when looking at it in a variety of ways. Our materials consist of text, pictures, animations, etc. Supplementing words and pictures with an expert speaker might provide additional help for difficult points. In the same vein, a non-gratuitous video clip can break up the monotony. Although the materials are fairly interactive, with reading, animations, simulation programs, diagrams, quizzes, and lab exercises, they can still benefit from an interlude of this type. And finally, though we intend to primarily use this tool to provide clips and not full topic lectures, some lectures will never be transformed into Web materials unless they are captured as live lectures and put online simply and easily. It is faster to videotape a live lecture and pair it with the speaker's slides than to develop web pages from the materials.

Currently, our display for speaker video clips (see Figure 1) consists of

- A video area, which can be fairly small. A head and shoulders video of a speaker can be very effective even in a small size, and many speakers are relieved to hear his/her face will not fill the screen.
- A table of contents, which we include even when the clip is very short, since it makes more sense to be able to pick and choose from a lecture. The table of contents is always placed on the left to promote the comfort level gained by displaying this piece where most people are accustomed to finding it.
- The supporting materials, either a set of Web pages or PowerPoint slides. Before we began using Microsoft Producer, we made the assumption that we would have to use HTML pages to avoid porting and converting issues. The addition of PowerPoint slides is a welcome change for some content developers, and sometimes the only way we can capture material from outside speakers. In addition, it's easier to add timed annotations to PowerPoint slides.
- A small HTML section which contains typical Web page information, such as date, copyright, and a link to return to the home page

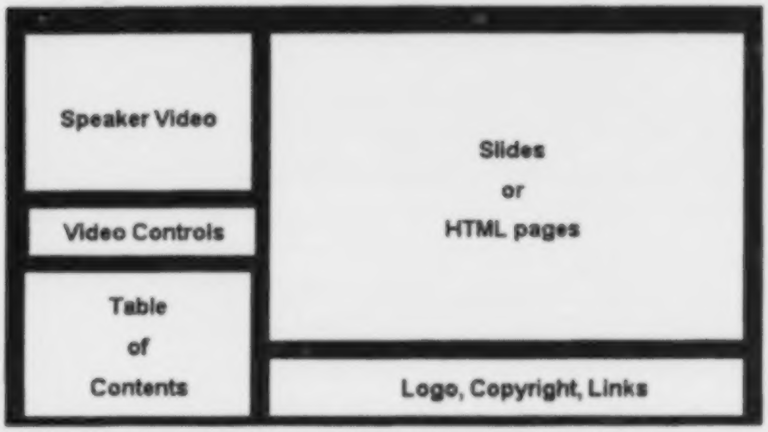

Figure 1: Diagram of display for speaker video clips

Additional design possibilities we are experimenting with are primarily in how we capture the speaker video. Methods we have, and plan to try include:

- A staged video shoot, where the speaker lectures to the camera in a quiet room. This method gives the opportunity to control the set and lighting, redo lines or whole sections, and edit the resulting video.
- Live lecture, where the speaker is talking to a live audience, and the camera is moved to the location as needed.
- Live lecture, where the room is always video-capture ready, with recording equipment always in place.

We have found that lighting is an important consideration. It is easier to adjust lighting levels in a staged video shoot than in a lecture room, where the lighting on the lecture screen often overpowers the lighting on the speaker. In delivery, the speaker in a staged shoot speaks to the person viewing the Web page, while in a live lecture the Web video often suffers. On the other hand, in a live lecture the speaker is often more animated; our speakers tend to be more wooden when speaking to a camera. Finally, in a staged shoot, the director can place the speaker in a chair; in a live shoot, the camera operator must be either very alert and skilled in tracking a moving speaker, or settle for a wide shot, resulting in a very small speaker image on the web page. However, the decision usually is not based on these issues, but rather what time, resources, and the speaker will allow.

Costs, Problems, Solutions

We began working with a browser tool and writing scripts to create the layout and presentation we were seeking. However, generalizing the scripts was time consuming, and the indexing table of contents we developed was too complicated and error-prone. In contrast, Microsoft Producer met our design goals, and is a free download for Microsoft PowerPoint 2002. To run the tool requires only Microsoft PowerPoint 2002.

To run the resulting web page requires

- Windows 98 or Windows NT 4.0 or higher
- Windows Media Player 6.4 or higher
- MSIE 5.0 or higher

This may seem like a strict set of requirements, but we felt that it would be too cost-prohibitive to develop our own tool that would reach a wider audience. Regardless of the solution, some percentage of Web page viewers would not be able to view the video clips. For clips containing content critical to the topic, we will continue to provide the materials in an alternate format, usually a series of still graphics and text.

BEST COPY AVAILABLE

We have seen by entries on our registration forms that the playback restrictions still allow us to reach the majority of our users; however, we will continue to track this number, as well as results from larger online surveys. In our case, the target is the equipment in homes and offices, for both our users and our potential users. Increasingly, this type of material is being put on CD, as well, for distribution at trade shows.

Research Plans

At this point most of the major questions have been answered. We have chosen a tool to produce the video clips, decided on two basic designs, and have begun to create production pieces. However, there are further issues to investigate:

1. The types of information which benefit most, e.g. complex concepts or procedural examples
2. Most instructive video clip components, e.g. speakers, or screen capture, or audio enhancement
3. Best layout and sizing for the various components
4. Most effective clip length

We expect additional issues will arise during research.

One area discussed that has not been investigated is finding a good way to encourage and allow the viewer to try a procedure while it is being explained. This will be the next new area being investigated.

Future Work

We are currently both creating production pieces and continuing to research issues such as those described next, with the goal of continuing to improve and refine our use of video clips. Valuable suggestions for evaluating online multimedia are included in (Kennedy 1999) and (Weston 2001).

Is the layout both clear and aesthetically pleasing? Are the major elements sized appropriately? Have we chosen the most readable font type and size? Is it clear how to navigate the page? Do the controls work as expected? The first three questions can be explored by showing the test group several possible layout schemes. Navigation and video controls can be tested by first watching each tester experiment, then tracking steps taken to navigate to a particular place in the clip; did the person choose the easiest method? These evaluation methods are described as direct observation and think-aloud interviews (Weston et al. 2001). We expect that for most of these issues we have already found the best solution, because we chose the conventional layout to increase comfort from the outset; e.g. the table of contents is at the left as expected, the footer on the bottom, and the video controls have the standard look and placement.

Which playback speed gives best quality without exceeding the bandwidth limits? Is it better to have one speed that is best for the majority, to auto select a speed based on connection type, or to let the viewer choose a speed? What is the ideal length of a clip? The best overall speed is difficult to define, because there is a wide range of target hardware and software, and it keeps changing; otherwise this would be the ideal since it is the simplest, least error-prone solution. One way to learn the preferred choice is to present all of these possibilities, and track web hits for what is chosen most often. It is expected that the auto-selected speed will be most popular, because I have learned through working with small test groups that even technically-savvy people are not sure which speed is best for them; they prefer to have this choice made for them. The ideal length of a clip can be tested by both watching and testing participants. The best length is expected to be less than five minutes; anecdotal feedback confirms that if a web clip is longer, attention will stray to email and other distractions. A study on using technology for language study (Ng 2000) found that PowerPoint presentations longer than twenty minutes were found to be very boring; ten minutes or less was advised. And although the broadband connections are continually improving, it is recommended that video file sizes be no larger than 320 x 240 for higher speed connections (Williams 2002).

And most important, does the use of video clips enhance understanding? Do "friendly faces" lead to improved or increased interactions in other parts of the course? Do clips interspersed in other web materials help keep the reader engaged in the module? What types of information are best presented this way, introduction, concepts, or topics with graphic elements? Testing will consist of checking whether modules with clips are completed more often than those without, reviewing the number of questions and tone for modules with and without a person associated, and comparing test results for modules that have video clips versus those with images and text. It is expected that this set of questions will be the most difficult to answer definitively, but that some level of improvement will be seen in all areas. A study on remote lecture presentations (Willie et al. 1999) found that presentations that include slides with sound and video have a higher hit rate than any other presentation type.

Author Biography

Susan Mehringer is a Senior Technical Consultant at the Cornell Theory Center, where she has been since 1987. Her current projects include work on the Virtual Workshop, including developing modules, consulting, and assessing WWW statistics; testing new systems and software; consulting; and developing and delivering training materials.

Self and Peer Assessment in an Online Collaborative Learning Environment

Abstract

A challenge in online collaborative learning teams is assuring that all members of the virtual learning team are actively engaged and contributing to the work of the team. One strategy to hold individual members of a learning team accountable for their contributions is through the use of peer and self evaluations. This paper provides a summary of an analysis of peer and self evaluations as part of an ongoing study of the use of peer and self assessment in online collaborative learning environments. The subjects of the study were on-campus and off-campus students who were enrolled in a web-based graduate course in collaborative learning. Based on a factor analysis of repeated self and peer evaluations, two factors were identified. The present study focuses on developing a deeper understanding of the two factors. The nesting of the self and peer evaluations and the dependency of the repeated measures data guided the use of a hierarchical mixed effects linear model with the two factor scores as the dependent variable and self or peer, team, assessment time, gender and campus presence as the predictors. Among the findings are that students change their evaluations of themselves and peers over time, showing more differences as time goes on. Gender differences are also noted in their scores. Off campus men decrease their task performance and their contribution to the positive social interaction with time.

Introduction

There is growing interest in the use of collaborative learning in web-based courses. Among the challenges posed by the use of virtual learning teams is assuring that members of the learning team actively participate and contribute to the team's learning projects. As part of ongoing research on the use of self and peer assessment in online collaborative learning environments, this study is focused on an analysis of factors related to self and peer assessment in a web-based graduate level course on computer-supported collaborative learning. Factor 1 relates to the active process of engagement in actions that result in the successful completion of collaborative tasks in the online course and Factor 2 relates to the social dimension of human interaction required for the positive and successful interaction in groups. Factor 1 appears to be the online reflection of the personal characteristics of Instrumentality and Factor 2 of Expressiveness.

The subjects in the study included: 1) on-campus students who were enrolled in degree programs in a large urban Southwestern research university; and 2) off-campus students who were enrolled in a web-based degree program in instructional technology offered through the university system. The virtual learning teams formed in the course were balanced with both on and off-campus students as well as other factors such as gender, technology expertise, and cultural background. 75% of the students were women and 25% men.

There has been growing interest in the use of peer and self assessment as a tool to hold individual members of a collaborative learning team accountable for their contributions to the team's learning projects.

Assessment may serve three purposes. Assessment may be used as the basis for allocating a grade (a form of summative assessment), to provide feedback to guide or improve practice (formative assessment), or to compare the effectiveness of curriculum elements (comparative assessment). (Wolz et al., 1997, p. 62). In this study, the peer and self assessments were used in part to determine their grade and, more importantly, as a means of providing group members with feedback related to their efforts and work on online team projects.

Van Merriënboer (1997) conceives of self-assessment and peer-assessment as complex skills or as a skills hierarchy. He suggests that self assessment can be defined as the students taking responsibility for monitoring and making judgments about characteristics of their own learning. Students are required to think critically about what they are learning and to identify performance standards, and to apply them in the assessment of their own work. Van Merriënboer defined peer-assessment as an assessment in which the student takes responsibility for making critical judgments about the learning of peers and applying the agreed on standards to the work of their peers. (Van Merriënboer, 1997).

Sluijsmans & Moerkerke (1999) report that students become more involved in the learning and in the assessment process. They find that self-assessment promotes more reflection on one's own work and products of higher quality. Boud (1990) stresses that higher education assessment practices need to be compatible with the curricular goals. Sluijsmans_& Moerkerke (1999) state that one of these goals should be that students take responsibility for their own learning and at the same time evaluate their own learning at different phases in the instruction process.

Current Instructional technology perspectives of learning (e.g. Brown, Collins & Duguid, 1989; Duffy & Jonassen, 1992; Brooks & Brooks, 1993; Duffy & Cunningham, 1996; Jonassen, 1996; Maddux et al, 1997) leads us to view knowledge as constructed uniquely by the individual, in multiple ways, through a variety of authentic tools, resources, experiences, and contexts. Social interaction introduces multiple perspectives through reflection, collaboration, negotiation, and shared meaning. If we consider that learning is both an active and reflective process, and that the reflection in the personal learning process is a key component and together with the process in which the peers engaged can be used.

The impact of individual characteristics on learners' success in hypermedia environments has been documented in Dillon and Gabbard (1998) review of the hypermedia research literature. Hartley and Bendixen (2002) state that there is a need for better conceptualization of the impact of learner attributes like self-regulation and epistemological beliefs in new hypermedia learning environments, and also there is a need to examine how different learners can benefit or not benefit from their use. They argue that it is essential to better comprehend how learners' characteristics impact their ability to succeed in environments that are very different from traditional learning situations and they stress the importance of looking at characteristics that research demonstrated to be important in learning.

The online medium seems to influence collaboration along several dimensions. Verdejo (1996) emphasizes the verbal exchanges among learners, centering collaborative learning on a "conversation or dialogue paradigm". Following his view, if we consider learning as a process that occurs in a reflexive dialogue, then the conversation precedes the action. Some of the time we engage in conversation with our own selves and we prompt ourselves to action. Other times the conversation or exchange of words -the social interaction- becomes like the glue that bonds a community. At the same time, the social interaction is the building block that keeps together the learning community and through which learning occurs and products are developed.

Recently, Menchaca and Resta (2002), borrowing from earlier gender research that described the personal characteristics of masculinity and femininity (Spence & Helmrich, 1978), lately named "Instrumentality" and "Expressiveness", reported two similar factors found in a study of the peer and self Online Teamwork Assessment Scale (OTAS). In their initial exploratory study, two personal characteristics "Instrumentality" and "Expressiveness" appear as the OTAS factors and seem to be determining the online interactions of students in online collaborative learning groups.
The self and peer assessment data seem to be measuring two constructs underling the process of online collaborative learning work: Instrumentality and Expressiveness. The high presence of both personal characteristics "Instrumentality" Factor 1 and "Expressiveness" Factor 2 expressed in action and interaction is important for team success in online learning environments.

The successful attainment of tasks and positive social interaction in online learning communities requires the presence two dimensions: One, a self management personal dimension or "Instrumentality", similar to the personal characteristics called masculinity by Spence & Helmrich (1978). Instrumentality leads learners to be involved and accomplish tasks that promote the team goals. Two, a social interaction skills dimension or "Expressiveness" previously called femininity, necessary to maintain the positive social climate. The electronic world of work shared by modern men and women, requires the exercise of instrumentality for successful professional activities. It is also important to maintain satisfying personal relationships in a promotive social climate. Effective team work is enhanced through positive expressiveness and empathy that promotes constructive interaction and the well being of others. Both characteristics represent the sine qua non ingredients of successful interaction and attainment of the group common goals (Menchaca & Resta, 2002).

Materials and Methods

When faced with the task of self assessment (SA) or peer assessment (PA), students from diverse backgrounds experience a significant degree of difficulty with the task. Self or Peer Assessment requires a learning process for the student to become comfortable with the assessment task. Gender of the peer evaluator may also be a factor. The following questions are important in developing a better understanding of the use of peer and self assessment.

- Does peer and self-assessment carried on in an online collaborative community of practice reflect the team interaction process?

- What does the repeated peer and self-assessment process reveal of the teamwork process? Is there a training effect on the student ratings over time?
- Do self assessment (SA) or peer assessments (PA) provide significantly different results?
- How do peer and self-assessment vary across time for different teams, campus presence and gender?

The course used in the study was entirely web-based with all course materials made available and all communication taking place online. There were 22 students in the course and they worked together in completing four projects. Three fourths were women. Roughly half were students who were on-campus students and the other half were distance education students from areas across the state and country. Web-based forms of the Peer and Self Online Teamwork Assessment Scale and rubrics were used at the end of each project by students in performing the peer and self assessment. Peers also conducted assessments of the other teams products as well as their own at the end of each project. Student's grades were composed of both individual and collaborative scores. The assessments were anonymous and only the student and the instructor could view the peer assessment scores which were based on the average of the ratings of the self and peer assessment.

The data analysis focused on understanding how the factors changed throughout the repeated measures of the course, between self and peer assessment, gender, campus presence and teams. A hierarchical mixed effects linear model was used as indicated by nature of the nesting and repeated measures of the peer and self assessment data. Because evaluations of the same person are similar, evaluations of peers coming from the same student are similar and the self evaluations are also similar, we selected a data analysis model that takes into account the nesting and dependencies of the data. The rating a student makes of peers reflects personal attitudes, beliefs and interpersonal style. In the same manner, a student views their own performance and contributions through a uniquely personal perspective.

Table 1. Covariance Parameter Estimates

Variation due to	Estimate	Standard Error	Z Value	Probability of Z
Student	0.02724	0.01196	2.28	0.0114
Evaluator	0.01100	0.004957	2.22	0.0133
Residual	0.1100	0.006079	18.10	<.0001

The mixed effect hierarchical model had the two factors of collaborative teamwork, instrumentality and expressiveness as the dependent variable. In the model the predictors were: self or peer evaluation, assessment time, team, gender, campus presence, and the interaction between self/peer by time and gender by time interaction. In order to be able to simultaneously explore the two factors a dummy variable was created, Whichfact that stands for which factor. Which Factor was significant in this model (Whichfact $F_{1,655}$ =

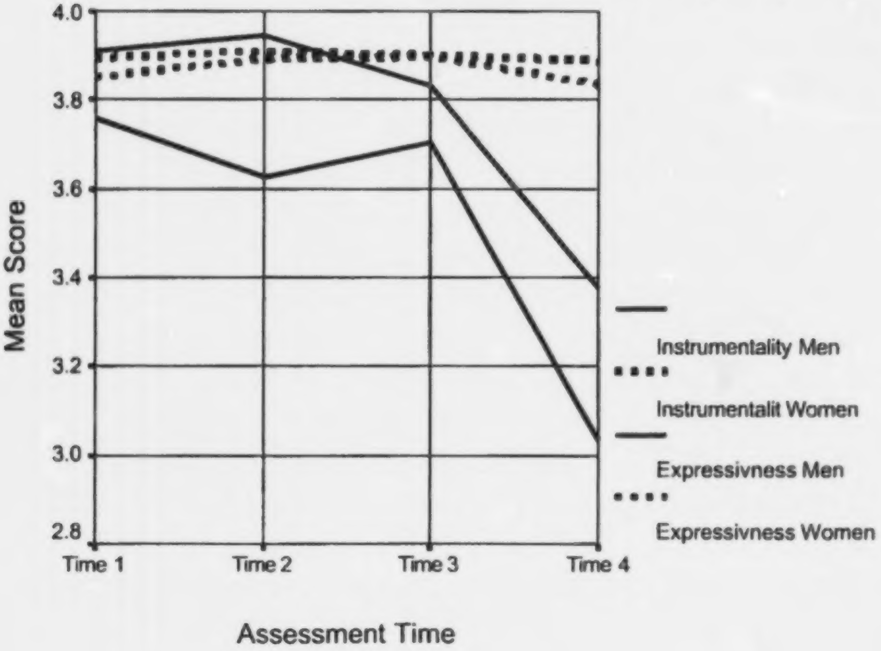
12.39 p = 0.0005 Table 2). More variance (variance for Student = 0.027 Table 1) is explained by the student then by the evaluator (variance for Evaluator = 0.011 Table 1).

Table 2. Type 3 Tests of Fixed Effects

Effect	Num DF	Den DF	F Value	Pr > F
SELF	1	655	0.53	0.4689
TIME	3	655	22.93	<.0001
GENDER	1	655	8.80	0.0031
TEAM	5	655	0.85	0.5160
INCAMPUS	1	655	1.41	0.2359
SELF*TIME	3	655	3.40	0.0174
TIME*GENDER	3	655	32.03	<.0001
WHICHFAC	1	655	12.39	0.0005

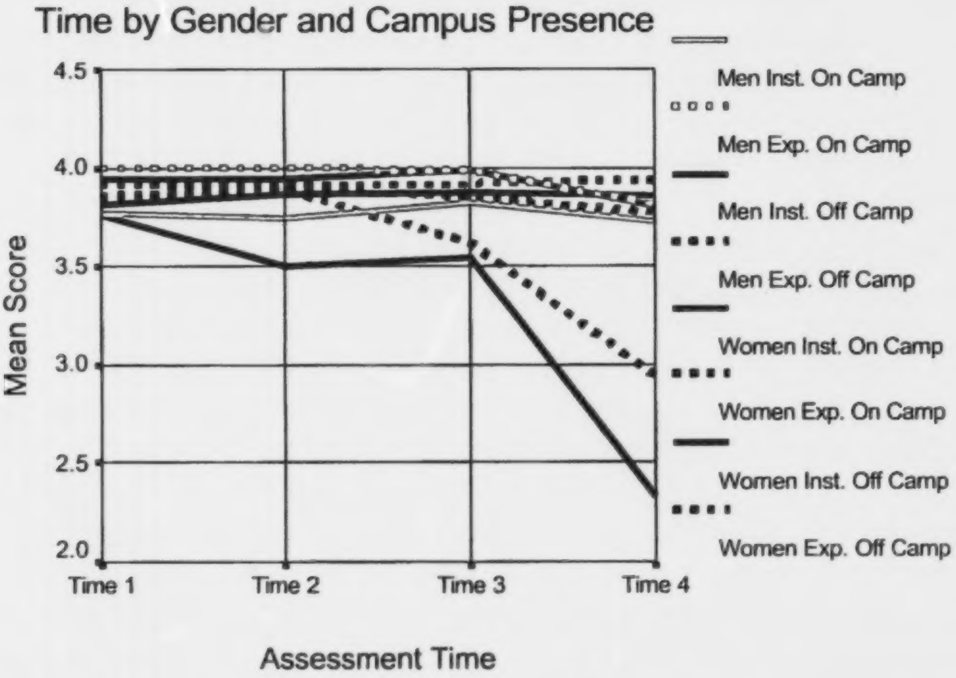
Through repeated practice on peer and self assessment over time, students learned to perform the evaluation process to reflect their assessment of the differential performance of others (Self by time $F_{3,655}$ = 3.40 p =.0174, Table 2). The main effect of Self versus Peer was not significant (Self by time $F_{1,655}$ = 0.53 p =.0.4689, Table 2).

Figure 1.Mean Factor Scores Change by Time



However, it is interesting to note that in some instances of missing data, when a student gives evidence online of not sharing their teamwork load rather than completing a self assessment in which they would have difficulty in rating themselves high on very specific indicators of active contribution to the team, they would choose to not complete the self evaluation.

Figure 2 Mean Factor Scores Change



The data also suggests the possibility of cross-cultural differences in the assessment experienced by students. There are some indications of reluctance to rate peers other than at a high level by some students. Further research needs to be conducted across students with different cultures to determine the extent to which culture may represent an important factor in peer evaluation.Students varied in the way they performed the evaluations over time (Time $F_{3,655}$=22.93 p <.0001Table 2 and Figure 1). At the end of the course students assigned lower scores to themselves and to classmates they viewed as not performing according based on criteria presented in rubrics for a high score. Men and women also differed in the way they were evaluated by their classmates (Gender $F_{1,655}$ = 8.80 p = 0.0031, Table 2 and Figure 1). Gender differences interacted with evaluation time (Time by Gender $F_{1,655}$ = 8.80 p = 0.003, Table 2 and Figure 1). Women's scores tended to stay high while men's scores tended to decrease over time although all peer and self assessment tasks were performed with the rubric for the quality of their collaboration.

The analysis indicated that students change the way they evaluate themselves and peers over time. In the process of self and peer assessment, students reflected on the performance of team members toward their goals (Instrumentality). The quality of team social interaction (Expressiveness) is also reflected in their observations of performance of their peers. Factor 1 relates to the active process of engagement in actions that result in the successful completion of tasks and Factor 2 relates to the social dimension of human interaction required for the positive and successful interaction in groups. In the mixed effect hierarchical model used no significant differences were found between teams (Teams $F_{5,655} = 0.85$ $p= 0.5160$) and campus presence (Campus $F_{1,655}=1.41$ $p = 0.2359$, Table 2).

In summary, the analysis of the self and peer assessments within a web-based course indicates that there is increased differences in peer and self evaluations over time that may reflect a training effect of students becoming more comfortable and competent in performing peer and self evaluations. It is also interesting to note consistent gender differences in peer evaluation. Also of interest is the observation that off-campus male students tend to decrease their task performance and contributions to positive social interaction of the team over time. The questions raised by these findings will be examined in further studies of the peer and self assessment process in online collaborative learning teams.

ELearn: A collaborative educational virtual environment

Anna Michailidou & Anastasios A. Economides
{michan,economid}@uom.gr
Information Systems
University of Macedonia
Thessaloniki 54006, Greece

Abstract: *Virtual Learning Environments (VLEs) that support collaboration is one of the new technologies that show great interest, concerning the innovative methods that gain ground in every aspect of educational procedure. In this paper, we present ELearn, a collaborative virtual learning environment for teaching e-commerce that has been developed using Active Worlds. We have constructed a virtual school using an environment that integrates the appearance of the virtual world, the web pages that are connected with specific objects in the world and the capability of synchronous chat among the users. Collaboration and interaction were two of the most significant matters taken under consideration, due to their important role in educational procedure. An evaluation of the environment is also included, with regards to specific criteria that we have developed for evaluating VLEs.*

KEYWORDS: COLLABORATIVE VIRTUAL ENVIRONMENTS, EDUCATIONAL PROCEDURE, VIRTUAL REALITY.

1. Introduction

The evolving growth that occurs in network and communication technologies leads to their enhanced usage in many and different aspects of human activity. One of the technologies that show great interest is Collaborative Virtual Learning Environments, which is used in various aspects, such as tele-education. Virtual Learning Environments (VLEs) [1], are learning management software systems composed of computer-mediated communication software and on-line methods of delivering course material. The implementation of innovative pedagogical practices is a response to the social needs for educational change [2]. Participants are experiencing new ways of learning and communicating with teachers by organizing the learning environment in a different way, based on several technological innovations.

2. A short description of the tools that were used for the lessons development.

ELearn was the name of the virtual world that has been developed at the University of Macedonia (Thessaloniki, Greece), with the purpose of teaching some of the basic aspects of electronic commerce.

Active Worlds [3]-[5] environment has been used for the development of the lessons, using virtual reality. This environment integrates at the same window, the appearance of the virtual world, the web pages[1] that are connected with particular incidents regarding the virtual environment and even the prospect of synchronous chat among the users (Picture 1).

The ASP language was used in order to achieve the lessons administration [6]. In cases, where an application is used by a group of users, it is necessary to develop a strong administration tool. In the first page of such a tool, the opportunity of choosing any of the offered functions must be given. In such a case the following functions must be considered: the opportunity of adding - removing users (students, teachers) and even changing some of their elements, such as their address or phone number. Only the lessons' administrator is entitled of using the above. On the other hand, a user should have the ability of searching and finding information concerning the teachers or the students.

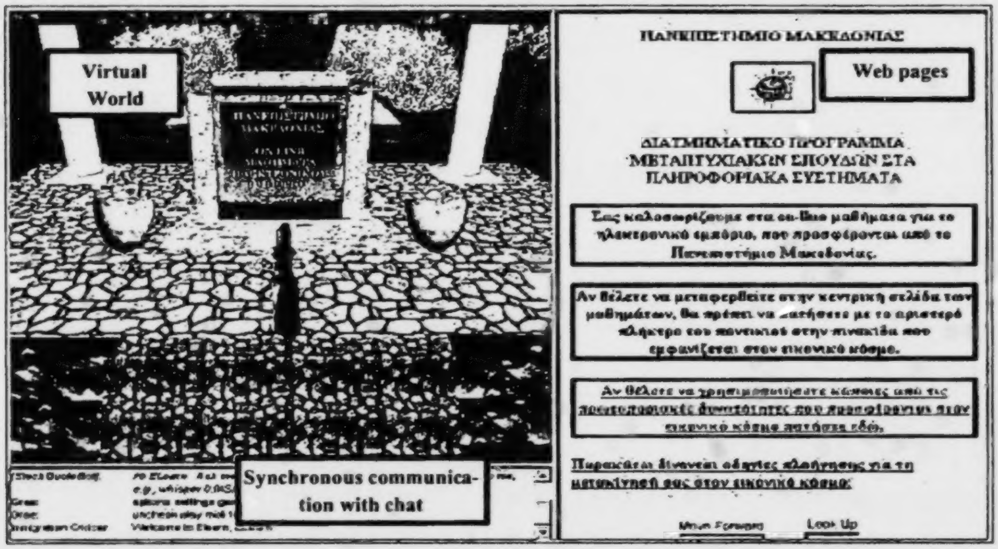
The web pages that are integrated in the Active Worlds environment have been created with the use of Microsoft Front Page 2000. The first page, having the role of a starter page, includes the following: Lesson map, Search, Information, On line enrollment, Administration, Communication and On line lessons of Electronic Commerce, which is the main page, concerning the lessons' development.

---

[1] Internet Explorer has been used for the development of the web pages.

BEST COPY AVAILABLE

- The **Lesson Map choice** consists of the contents of the two chapters that have been created regarding electronic commerce.
- The **Search choice** concerns the searching for information lying in the lesson pages.
- The **Information choice** includes elements of general interest, concerning the lessons.
- The **On line enrollment choice**, gives to a future student the opportunity to enroll for the lessons and also to a future teacher the opportunity of joining the teachers' team, with the objective of helping in the lessons construction.



ΠΑΝΕΠΙΣΤΗΜΙΟ ΜΑΚΕΔΟΝΙΑΣ

ΔΙΑΤΜΗΜΑΤΙΚΟ ΠΡΟΓΡΑΜΜΑ
ΜΕΤΑΠΤΥΧΙΑΚΩΝ ΣΠΟΥΔΩΝ ΣΤΑ
ΠΛΗΡΟΦΟΡΙΑΚΑ ΣΥΣΤΗΜΑΤΑ

Σας καλωσορίζουμε στα on-line μαθήματα για το ηλεκτρονικό εμπόριο, που προσφέρονται από το Πανεπιστήμιο Μακεδονίας.

Αν θέλετε να μεταφερθείτε στην κεντρική σελίδα των μαθημάτων, θα πρέπει να πατήσετε με το αριστερό πλήκτρο του ποντικιού στην πινακίδα που εμφανίζεται στον εικονικό κόσμο.

Picture 1.: The integrated environment, which was used for the lessons development.

- The **Administration choice** gives the opportunity of administrating the lessons (adding, deleting and changing information concerning students and teachers by the administrator - a password is necessary - and searching student - teacher - information - something accessible by any user-).
- The **Communication choice**, offers to any user the opportunity to communicate with the administrator by sending email and ask specific questions or make certain remarks.
- The **On line lessons of Electronic Commerce choice** leads to the central page concerning the lessons development. From this page, someone can choose any of the following choices:
  - ⇒ **Introduction:** it includes general information about electronic commerce.
  - ⇒ **Contents:** it includes the content of the lessons.
  - ⇒ **Chapter 1:** this chapter consists of four paragraphs with text, images and navigation links. The contents include information about the World Wide Web, definitions of electronic commerce, the necessity and the advantages and disadvantages of its usage.
  - ⇒ **Chapter 2:** as in the first chapter, there are also four paragraphs and consist of text, images, tables and navigation links. Specifically, the paragraphs refer to the market research that should be done before the construction of an e-store, the strategic planning which proceeds, the right presentation in the world wide web and the final stage of actual making the on line store. Additionally, in the fourth paragraph, two videos are included, as examples of two on line electronic stores.
  - ⇒ **Glossary:** it consists of some basic terms in alphabetical order, concerning the electronic commerce lessons.
  - ⇒ **Help:** it includes information on how the user can get help, through email to either the administrator or any of the teachers or students.
  - ⇒ **Exercises:** in order to make the application more educational, two tests are included, corresponding to the first and second chapter of the lessons. These tests consist of exercises, where the student can type the answer to the appropriate orthogonal frame and also of multiple-choice questions, where the student must choose the right answer from a group of choices.

BEST COPY AVAILABLE

⇒ **Library:** it includes sites concerning electronic commerce in a structured way so the users can find information regarding their interests.

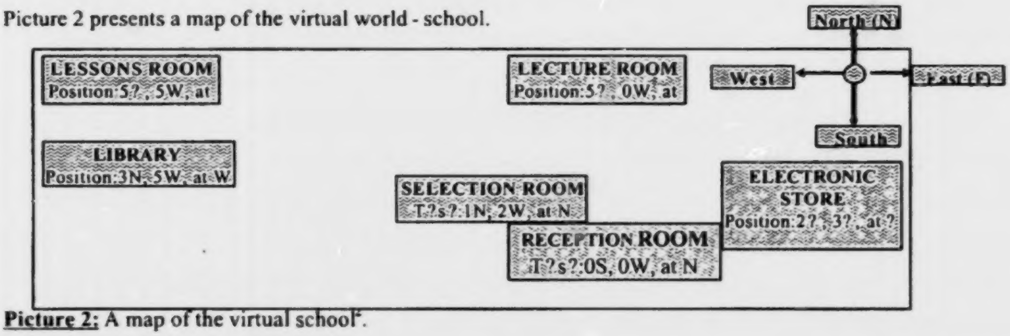
⇒ **Discussion Board:** it is a tool that can enhance collaborative learning. It can be used for creating discussions among interested users.

⇒ **Virtual Chat:** it also enhances collaborative learning. It can be used for synchronous chat between the participants.

For the conjunction of all the tools that concern the development of the lessons, the Active Worlds environment has been used [3]-[5], [7], [8]. The Active Worlds environment helps the user to create a virtual world and visit a number of other worlds available.

3. ELearn: A Virtual World of Electronic Commerce. Description.

Picture 2 presents a map of the virtual world - school.



Picture 2: A map of the virtual school[2].

There are six spaces to the virtual world: the reception room, the selection room, the lessons room, the library, the lecture room and the electronic store.

- **The reception room:** it contains an ancient temple with a sign placed at the center, which is welcoming the user. Additionally, at the chat window, the following massage appears: «WELCOME TO THE WORLD OF ECOMMERCE!» and a corresponding sound is listened.
- **The selection room:** it is connected with a web page that is also the main page of the lessons and includes the following choices: Lessons Map, Search, Information, On line Enrollment, Lessons Administration, Communication and On line lessons of Electronic Commerce, which is the central page that refers to the development of the lessons. Each of the previous choices corresponds to an object at the selection room. If someone presses with the left mouse button on an object, a corresponding web page will appear.
- **Lessons room:** it includes objects with signs, that each one of them is connected to a web page that contains information according to the specific topic of interest. The topics that are included are the following: Introduction, Contents, Chapter 1, Chapter 2, Glossary, Help, Exercises, Library, Discussion Board and Virtual Chat.
- **Library:** it includes sections filled with books. Each object that contains books is divided in three sections. In the first section, a sign is placed that informs the user for the contents of the next two sections. If the user left clicks on a section, he will be able to inspect the information that corresponds to that particular choice, at the web page window.
- **Lecture room:** the basic objects of the lecture room are the signs, the computer desks and the projection board. Every sign contains a paragraph title, from the first or the second chapter, concerning electronic commerce. If the user presses with the left mouse button to a sign, a web page concerning the correspondent paragraph will appear. If the user's avatar collides to a sign, a narration, concerning the subject will begin. Apart from the signs that are relevant to the paragraphs, there is one additional sign that refers to an example of an electronic store and two more signs, one for the use of the Discussion Board and the other for the Virtual Chat.

At the left side of the lecture room, there are **desks with computers**. If the user approaches a computer with the mouse pointer, an explanatory sign will appear that gives information on what will happen if a computer is pressed. The **projec-**

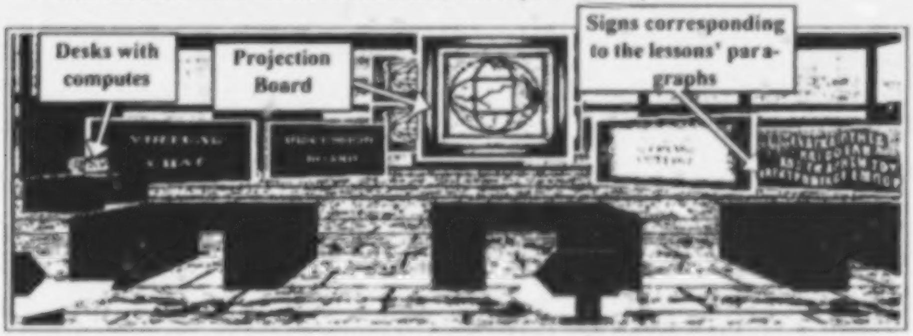
---

[2] This map refers to the position of each room at the virtual school, according to the north, south, east and west coordinates and to the direction of the avatar, the first time he/she visits the particular room.

BEST COPY AVAILABLE

tion board is located on the center of the room in front of the desks (picture 3). In the lecture room, two lectures are attended, concerning electronic commerce. The projection board is used for the slides change that concerns the lectures.

- **The electronic store:** it is an example of an electronic store that is located to the virtual world with the purpose of giving to the students the opportunity to understand how an electronic store is constructed in the «real» world. The store that is described offers cars, motorcycles and bicycles.

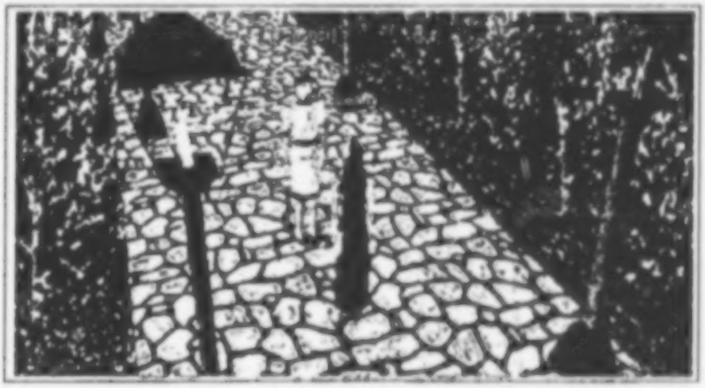


Picture 3: An aspect of the lecture room, where the basic objects are being viewed.

The Active Worlds environment offers the opportunity of using a Software Development Kit (SDK) [9]-[12], that allows the programmers to develop applications that can interact with the virtual world's environment. The most common type of application for the SDK is a bot.[3] Three (3) bots exist at the virtual world.

The first bot is named **Teacher** (Picture 4) and it is built for the purpose of helping the students during their navigation to the virtual world. The user can ask the teacher various questions concerning electronic commerce. The subjects that the teacher could be asked for, appear at the chat box, once the user types Help. A real teacher may manipulate the Teacher bot and therefore a discussion could be build between the teacher and some other users, based on any subject concerning the lessons. The teacher can also examine the students by asking them questions unknown to them. Additionally, a student can «whisper»[4] to the teacher and become recognized only by him.

The second bot is named **Salesman** and it appears whenever another user (avatar) enters the e-store. The salesman can give information concerning the products that are offered in the electronic store and advise the user of how he/she might fill an order form. The salesman can be used with the same way as the teacher.



---

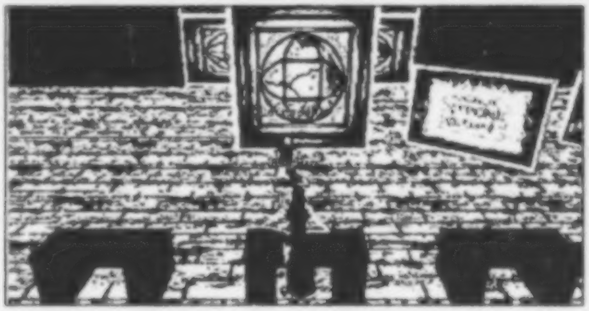
[3] A bot is typically an avatar that inhabits a virtual world and interacts with users. It is driven by a computer program, instead of a human being (citizen or tourist).

[4] A whisper is a chat massage sent directly to another user. When one whispers, the recipient is the only person who can hear what he says.

BEST COPY AVAILABLE

Picture 4: The teacher and the student coexist in the virtual world.

The third bot is named **Lecturer** and has the capability to give lectures, in the Lecture room (picture 5). The Lecturer can synchronize text spoken by the bot with changes in objects or .jpg images. Therefore, a virtual «slide show» can be created. The Lecturer's bot communicates by normal chat, but its more powerful feature is the ability to whisper to the avatars that are located in the lecture room. As a result, any other avatar that exists in another room of the virtual store, for example the electronic store, will not identify the Lecturer.



Picture 5: A lecture, as it develops in the lecture room.

4. Discussion

The evaluation of collaborative VLEs is not a simple task [13]. Without a descriptive model of the ideal collaborative learning process, we cannot easily find indicators (either qualitative or quantitative) that will tell us whether effective learning is taking place. Additionally, on the level of evaluation criteria, the criteria themselves need to be changed and adapted according to new findings and new constrains that result from system development. Therefore, formative evaluation needs to be performed on four levels simultaneously: **the pedagogical - psychological level, the technical - functional level, the organizational - economical level and the social - cultural level.** [14].

The **pedagogical - psychological level** includes all the criteria, referring to the learning process itself. For example, criteria such as support of different didactic methodologies, how to represent and modify knowledge, tools to define learning goals, or support for different roles (learners, trainers, tutors) need to be assessed at this level. The **technical - functional level** includes criteria that refer to the proper functioning of a concrete system, e.g., criteria such as stability, required bandwidth, interface design, e.t.c. The **organizational - economical level** deals with aspects of organizational context and constraints, e.g. how efficient and cost effective are computer supported learning processes compared to traditional ways of training. Finally, the **social - cultural level** evaluates how a system fits into the overall learning culture and how its users from a motivational and emotional point of view accept it. A model of evaluating collaborative virtual learning environments has been developed [15] - [18], based on the previous factors. Table 1 includes the evaluation criteria at the first column and some comments concerning the ELearn environment at the second.

5. Future work

The development of software, that is build on collaborative virtual environments could be proven extremely useful in the educational procedure. The current research and commercial interest in developing CVEs that support rich social interaction in densely populated virtual worlds is an ambitious goal, one that requires addressing a variety of technical challenges [19].

Based on future growth, the conjunction of virtual environments with databases that are continuously enriched with new elements in order to be synchronous is an interest aspect [20]. Another capability that is of great interest is teleimmersion that integrates the technology concerning collaborative virtual environments with audio and videoconference and other computer power demanding, technical capacities. Also, the addition of smart behavior to the system with the usage of intelligent agents is something worth of studying. Pedagogical agents are of great importance and can be used in collaborative virtual environments, as they are represented with a character (avatar), or a specific object (for example, a book).

The ongoing research involving VLEs is worthwhile, considering that the networking of multi - participant, collaborative virtual environments appears to represent a significant trend for future applications [17].

Evaluation parameters	ELearn environment
a. Pedagogical - Psychological parameters	
a.1. Teaching theories (collaborative learning, adaptive, constractivistic or conceptual model of teaching).	Collaborative learning is supported with the inhabitancy of many avatars at the same virtual world and the use of synchronous chat. There is also the capability of using the discussion board and the virtual chat.
a.2. Organization of the teaching material (it refers to the purpose of teaching, the age of the students and the aims of learning).	The lessons were developed with the purpose of teaching the basic elements concerning electronic commerce to pre-graduate students. A further development of the content is necessary in order to expand the field of analysis.
a.2.1. Teacher tools (can teacher take part in the development of the lessons, is there any directions concerning teaching, can the students be graded on line, can the teacher make exercises, quizzes, e.t.c.).	The teacher can participate at the development of the lessons and give exercises or grade to the students on line. It is essential for the teacher to have some basic knowledge of the tools that must be used in order to use the environment, to make a new test, to communicate with another teacher or student, e.t.c..
a.2.2. Student tools (can the students use on line help, possess their own email, use discussion boards or virtual chat, use asynchronous or synchronous ways of communicating, have access to their grades, e.t.c.).	The environment supports collaborative learning and therefore the students can use both synchronous and asynchronous ways of communication. They also can get help (the bots are essential) concerning the lessons (a glossary and the contents of the lessons are available). Searching is also included in order for someone to find information concerning the theme of interest. More attention should be given at the monitoring of the students progress.
a.3. Evaluating of learning(can the student use the environment soon enough without the teacher's help, interact freely with the environment, use interactive tests, e.t.c.)	The usage and navigation at the environment is easy and pleasant, through the user's interface. The students can interact with the environment under certain constraints - for example, they cannot change the objects properties or build anywhere at the virtual world -. There are no interactive tests included at the time being.
b. Technical - Functional parameters	
b.1. Development characteristics (are there any multimedia elements supported - pictures, sound, video, e.t.c. -, can the software being used at different platforms - Unix, Windows NT -, can the software communicate with a database, e.t.c.).	Various multimedia elements are supported and the software can be used in different platforms as well. The capability of using the connectivity with a database was not examined.
b.2. Designing the interface (is the environment designed in a clear and interesting way, how cautious where the designers concerning the text, pictures and other multimedia elements that where used, is it possible to personalize the user with an avatar, do the environment support facial and body gestures, is immersion supported - with the use of special equipment (the stereoscopic helmet, the gloves) -, e.t.c..	There has been an effort of designing the interface with an interesting way, using common ways of interactivity with the environment (e.g. signs) but also provoking the student to explore and learn. The user can be personalized with an avatar, facial and body gestures are supported but immersion is not.
b.3. Support procedures (can the students and teachers be informed on the software usage, is there any technical support offered by the company, is the software and the sites being often updated, is there a satisfactory security, concerning the files transaction, are there any mirror sites, e.t.c.)	The students and the teacher can use help concerning the software usage and the technical requirements. The procedure of updating the contents and the security problem need more work. There are no any mirror sites.
b.4. Administration tools (are backup files supported, are there any tools that prevent unauthorized access to the server, is on line enrolling possible, is there a way of administrating the lessons - add, delete, update records -, e.t.c.)	It is possible for the lessons administrator to retain backup files of the virtual world, on line enrolling is possible and an administration tool is being developed. The security matter needs to be more analyzed and developed. Furthermore, the ability of adding, changing and deleting students and teachers is entitled only to the administrator.
c. Organizational - Economical parameters (is it possible for the organization to support server hosting, advertisement of the lessons, is there any pricing policy and on what terms the users are going to be charged, e.t.c.).	The lessons were developed at the University of Macedonia and therefore server hosting was supported. There wasn't any study made on advertisement and pricing policy.
d. Social - Cultural parameters (are the differences on religion, cultural development, language, age taken under consideration, e.t.c.)	The lessons are not related with religion but the development on the basis on different culture and language may be crucial for on line teaching. The language used was Greek because the lessons where addresses to Greek students, but the development on a different language might widen the prospects of the software usage.

Table 1: An evaluation of the ELearn environment.

P.Monthien@cs.ucl.ac.uk and A.Sasse@cs.ucl.ac.uk

Abstract: This paper investigates how computer support for vicarious learning can be implemented by taking a principled approach to selecting and combining different media to capture educational dialogues. The main goal is to create vicarious learning materials of appropriate pedagogic content and production quality, and at the same time minimise the financial cost and effort to produce such materials. We propose that multimedia and television production principles can be harnessed for this purpose. We report the results of 2 case studies on collaborative learning of television production in communication arts and diagram construction in computer science and analyse the problems encountered in the production and use of the vicarious learning materials created. We conclude that, if vicarious learning is to be implemented, the problems that educationalists face in creating appropriate materials needs urgent attention.

Keywords: courseware authoring, vicarious learning, collaborative learning, digital video, higher education.

Introduction

What is Vicarious Learning?

Vicarious learning (VL) is learning that takes place when one learner observes an educational dialogue between a tutor/lecturer and another learner (Mayes & Fowler 1999). In previous studies of vicarious learning, the evaluation criteria were entirely pedagogical, such as assessing the effectiveness of VL materials (Lee et al. 1999; McKendree et al. 1998; Stenning et al. 1999) and whether VL promotes learning (Lee et al. 1998). The research reported in this paper builds on these studies, and extends them to consider how best to implement computer support for vicarious learning (CSVL). The main goal of our research is to create tool support for VL materials that contain the appropriate pedagogic and production quality, and can be delivered with the skills, resources and equipment available to most educators.

What makes CSVL different from a video?

The main advantages of supporting the production and access of vicarious learning material via computes as digital video (DV) over conventional video are:

1. the ability to integrate this resource with other online learning materials – DV can contain URLs to online lecture notes or relevant online formative/summative assessment modules and
2. the possibility of personalising the learning material.
3. DV can be divided into chapters that are much easier to navigate through than conventional analogue video.

As real life interactions will be recorded, students will be able to relate directly to problems that they and their colleagues are having during that academic year. In the simplest form, CSVL allows students to revisit their collaborative attempts at tackling a problem. Such revisits strengthen their understanding of the topic by promoting the use of *episodic memory* (Tulving 1983). Episodic memory is a person's personal memory encoded with respect to specific time and place, i.e., remembering the lecturer explaining what episodic memory is on a hot summer afternoon in his/her office. Such memory is more resistant to forgetting. Additionally, students will also be able to view other groups' attempts at tackling the same or similar problems by either accessing materials from the current or previous academic years.

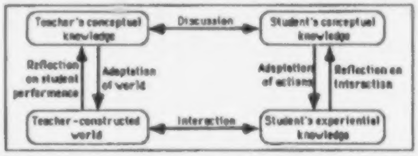
Producing VL Materials

The main aim of our research is to produce a design specification for a cost-effective CSVL system that can be easily implemented by individual or small groups of educators and is flexible enough to accommodate the specific needs of their teaching topics and student cohorts. The system also needs to be flexible enough to support installation in small rooms (individual tutorial) and medium-size rooms (group tutorials).

Why focus on these implementations of CSVL? VL has been shown to be effective in professional productions, e.g., Open University education programs containing brainstorming and debates between lecturers and students and public debates often discussing issues concerning current affairs. However, a lecturer who wants to use such programs can face several obstacles. Firstly, the content of the program may not suit the need of the students/courses that the lecturer is teaching. Secondly, the materials are not grounded in the students' own experience and therefore do benefit from the effects of episodic memory. Professional productions are also costly and require large amount of time and effort from a lecturer who wants to produce similar material. For this reason, our research is asking whether computer support can bring the benefits of VL to individual lecturers. If so, how can it be done? If not, what are the main obstacles?

Pedagogic Design

VL can form parts of various pedagogic designs. Since the main aim of our research is to investigate the various aspects of technology used for implementing VL, the Laurillard's model of learning (Laurillard 2002) was adopted and maintained through out for consistency. In this case, VL forms part of the on going negotiation of meaning between the lecturer and the students. A simplified diagram of this model is given below.



Teacher's conceptual knowledge
Discussion
Student's conceptual knowledge
Reflection on student performance
Adaptation of world
Adaptation of actions
Reflection on interaction
Teacher-constructed world
Interaction
Student's experiential knowledge

Figure 1: Simplified diagram of Laurillard's Model of Learning (Pennel 1996)

Another model of learning which may also be applicable is Wenger's Learning Architecture Model (Wenger & Snyder 2000), where students are working towards being part of a community of practice, in this particular case, the community of systems analysts and IT developers.

Perceived quality of production matters – a pilot study

Most video-based VL systems consist of video recordings of the interactions between lecturers and students, accompanied by notes on the topic under discussions, and perhaps the page of the lecture notes on the topic. Two such examples are The Dissemination System[1] used at Heriot-Watt University and a similar one at University of Edinburgh[2]. Both systems are used for teaching Human-Computer Interaction (HCI) courses. On the other end of the spectrum, the Classroom2000 project[3] at Georgia Institute of Technology demonstrates what high-quality recording and dissemination technology can deliver. By combining video/audio recording with time-stamped slides and annotation, the Classroom2000 project has managed to put the essence of a lecture online. However, this emphasis of putting lectures online means that Classroom2000 does not focus on student actions and feedback, which is essential for VL. Additionally, the system, requiring expensive equipment, is not cost-effective to implement in individual lecturer's or small tutorial rooms.

A pilot study was conducted to see how a simple production of a single-camera recording a tutorial session be perceived. Computer science students were shown some samples of videos containing vicarious learning resources and were asked to make general comments about them. In each video, a lecturer and a student have a staged dialogue on general HCI topics while seated around a table. At various points, either the lecturer or the student would refer to materials on pieces of paper or the whiteboard. The video was produced using a single static-angle video camera and, after encoding into RealMedia streaming format, shown on a 1-inch in diagonal window supported by mono sound. Some of the most prominent comments from the students concerning such a production were:

1. Poor sound quality made it very difficult to understand what each person was saying.
2. The video was so small and blurry that there was "little point in it being there".
3. It was impossible to see what was written on the whiteboard or the pieces of paper on the tabletop.

BEST COPY AVAILABLE

4. The content was perceived as "deadly dull."
5. It was hard work going through each video and picking out what the main message was.
6. Students said they would be reluctant to refer to such material, they would prefer to use lecture notes and books.

The pilot study revealed that the perceived quality of the material not only affects comprehension of the content being offered, but also its perceived practicality, i.e., whether such resource will be used or not. A previous study of real-time multimedia in a distance education context (Watson & Sasse 2000) found that perceived quality of materials can be affected by unsatisfactory audio quality resulting from incorrect setup of end-system audio hardware and equipment setup, rather than by network effects such as packet loss and jitter. Comments from students in this pilot study showed that perceived quality of recorded material can be similarly affected by insufficient end-system video hardware and incorrect equipment setup.

How to make a difference?

So what affects the perceived quality of video-based vicarious learning materials? This case study looks at the student's perception of the quality of materials in comparison with other materials such as lecture handouts, books and self-made notes. Audio/visual production variables play a crucial role in the perceived quality of the final material, We wanted to determine which variables affect students' perception of the quality of recorded instructional material, and to what extent.

Multimedia Production Principles

Reeves and Nass (1996) identified a number of factors that can influence the perception of multimedia material. In our view, the following are particularly relevant to authoring video-based multimedia:

1. **Image size:** larger images are evaluated more positively than smaller ones and better capture the viewer's attention. Additionally, content on larger images are better remembered than those on smaller ones.
2. **Fidelity:** sound quality was found to have more impact on the viewer's perception of the quality of the material being shown. More importantly, audio fidelity was found to affect attention to media and the viewer's memory for audio information.
3. **Synchrony:** viewers of videos containing audio-video asynchrony commented that people in the video were "less interesting, less pleasant, less influential, more agitated, and less successful in their delivery" than those in synchronized video. This is very significant, as educational materials should not have any of the attributes that have just been mentioned.
4. **Scene Changes:** scene changes can be used to provide structural cues to direct the viewer's attention as well as serving as markers in the viewer's memory. In order to create appropriate cuts and scene changes without using cameramen, it will be necessary to use more than one camera to capture the discussion.

Television Production Principles

Guidelines from the area of communication arts (or media studies) suggest that the number of camera angles also affect the viewer's perception of the quality of the production. The two main factors that have not already been mentioned are:

1. **Shot Selection:** Multimedia principles already point out that, if the production will be viewed in small windows, the camera should close in on the speakers to create the sensation of larger size. Television production principles add to this several points concerning the placement of cameras and how speakers should appear on screen (shot selection). These ranges from wide-angle shots used for orientation of the viewer to over-shoulder shots for suggesting relationship between speakers. Overall there are around seven main shots that can be used during an interview each with specific purpose (Armer 1990). Specifically in the context of this case study, it is also important to make sure that the camera shots that are used allow a clear view of any artifacts – such as models or drawings.
2. **Number of Cameras:** As well as shot selection, the number of cameras also influences the quality and style of production (Watts 1997). Single camera productions require a camera operator that can skillfully move around the set in order to film each speaker as he/she speaks without any obvious interruptions. In a two-camera production, camera movements are greatly reduced by "cross-shooting" (the field of vision of each camera appear to cross). Additionally, the camera operator can zoom in or out to get extra "over-the-shoulder" shots. However, if a third camera is introduced, the job of the camera operator becomes minimal or nonexistent. That is, it is possible to create all the necessary shots

with three cameras for an interview situation. If no camera operators are required, materials can be created without the camera crew associated with traditional video productions

Post-production Issues

In addition to multimedia and television production variables, there are some post-production design issues that may also affect the student's perception of quality. Compared with text, video and audio are slow media for transmitting information – reading a book yourself is much quicker than having it read to you. It is therefore necessary to provide navigational support to allow students to quickly access certain part of the material, without having to go through the entire content of the material.

Too Many Cameras?

Case Study 1 – TV Production Course, St. John's University, Bangkok, Thailand

According to television production principles, increasing the number of cameras will increase quality of production. *But is there a point of diminishing return?* In terms of return on investment, is the amount of information captured that much better when using three cameras than one?

An experiment was conducted to investigate how increasing the number of camera angles in video productions affects the students' perception of the quality of the production. Three cameras were used to capture 3rd year undergraduate communication arts students producing their first television program. Lecturers in this discipline usually introduce students to the theories of producing a "show" in the classroom, but it is difficult to teach students how things actually work or relate to each other in the studio. The aim of the video was to show fellow students the dynamics and the dialogues that go on within the control room – problems that other students encounter, how they solved them and how they make decisions within the group to accept certain takes. The point of the video is to minimize the amount of time students spend inside the studio learning how to produce a show rather than actually producing one. As studio time is rare and expensive, this will allow students to make better use of their studio time.

Experimental Setup

The production session takes place in two adjacent rooms – the control room and the studio. The producer, director, soundman, switcher and computer graphics supervisor work in the control room while actors, cameramen and stage manager work in the studio. It is the action in the control room that are of direct pedagogic relevance for this production, but the actions in the studio are also relevant in the wider pedagogic context. Three cameras were setup to capture the student's production session. The aim is to create for the experiment *three productions that differ only in the number of camera angles that are used.* Consequently, it was necessary to produce the three productions from just a single take to ensure that the content of the productions are identical. Each camera was positioned as follows:

Camera 1: Wide angle shot inside the control room with each person and control equipments visible. Each person has his/her back towards the camera as they are working on the equipments within the room. Additionally, a small portion of the studio room was also visible.

Camera 2: Wide angle shot inside the studio itself. This camera captures the actors, cameramen and stage manager.

Camera 3: Close up shot of each person inside the control room. Each person face, in contrast to camera 1's angle, is now visible.

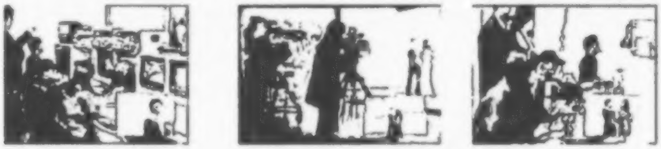

Figure 2: Screenshots showing the three camera angles used in the experiment (including PIP insert)

In addition to these three camera angles, it was possible to add another angle, which was drawn from the actual production that the students were creating – i.e., the show that they were making – this was presented as a picture-in-picture (PIP) insert. This is similar to being able to see what people are writing while they have a discussion around a whiteboard. From these three cameras and the PIP insert from the student's production, the following productions were created:

Production	Camera 1	Camera 2	Camera 3	PIP
1	X			
2	X			X
3	X	X		X
4	X	X	X	X

The productions are ordered according to the amount of effort it would take a lecturer to edit each production, where production 1 requires the least amount of effort. Once all the necessary productions have been created, twenty-one students were grouped into three focus groups. Each group viewed the following productions:

Focus Group	Prod.1	Prod.2	Prod.3	Prod.4
1	X	X		
2		X	X	
3			X	X

Students were not directly prompted to comment about the quality of the video but instead were first asked whether there were any differences between the two video productions.

Summary of Results

The transcripts of each focus group were analysed in terms of comments that the students made specifically about the quality of each production. There were significant differences in terms of perceived quality between production 1 and production 2, and between production 2 and 3. In both cases, increasing the number of camera angles resulted in the students thinking that the quality of the production had been improved. However, there were no perceived improvements in quality when moving from production 3 to production 4. As a matter of fact, focus group 3 actually said that production 4 was 'more boring than production 3'. This indicates that *while increasing the number of cameras does not always increase the perceived quality of the production, the number of cameras used does affect the viewer's perception of production quality.* The result suggests that the optimum setup for this particular case would be to use two cameras to capture the dialogue and one PIP insert to keep track of what the students are doing with props.

Analysis of Results

Why did the addition of another camera in production 4 not increase the perceived quality of the production? When breaking down the content of the video in terms of the Laurillard's model of learning, a pattern has emerged. If the content of each production is categorised in terms of the stages of interactions in the model, each additional camera angle in successive productions adds another stage of interaction of the model to the production – all except in the case of production 4. Production 2 adds the result of the student action, production 3 adds the actual action of the students in the studio, but production 4, while adding another camera angle, does not add a stage of interaction that has not already been covered by previous productions.

Consequently, in order to determine how many cameras will be needed to effectively capture a situation for use as vicarious learning material, it is necessary to *first identify what actions correspond to which part of Laurillard's model, and then implement the necessary technology to capture those actions.* For example, a 1-camera setup will be as pedagogically effective as a 2-camera setup when capturing a student and a lecturer talking about a concept, but a 2-camera setup will be more pedagogically effective should any written materials be introduced into the discussion.

Capturing Dialogues in the Real World

Vicarious Learning and Computer Science Education

Diagram construction is a major part in the syllabus of computer science and information technology students. Each year, students find it difficult to learn how to construct system models such as entity-relationship or UML diagrams. To help the students, many lecturers show common mistakes in diagrams constructed by students in previous years. But since the process of constructing such a diagram involves more than the finished product can communicate, most students acquire the ability to construct such diagrams only after several attempts of their own, with feedback from the lecturer. This type of feedback – delivered 1-to-1 or in small groups – is very demanding on lecturers' time. To get more learning revenue from this time-consuming process, the tutorial sessions were captured as digital videos, and integrated into course notes and online computer-aided assessment (CAA) system. In effect, students who are not present in the tutorial can vicariously learn the same material and more through this setup. Students can also acquire necessary skills by observing one of their colleagues constructing a diagram or, more often, by collaboratively constructing the diagram as a group. Additionally, if dialogues between the student(s) and the tutor/lecturer can be captured during an attempt at constructing a diagram, students who were not present will not only see the resulting mistakes but also how and why the mistake came about in the first place and of course, the reasoning behind constructing the final correct diagram as well! Hence, this particular case study looks at how best to produce Digital Video-*based (DV-based) vicarious learning materials* for teaching diagram construction in the field of computer science and what kind of problems lecturers face when producing video-based for such a course.

Case Study 2 – Systems Analysis and Design Course, University College London, UK

What kind of problems do lecturers really encounter when creating their own video-based materials? In order to investigate this issue, a case study was conducted. Rather than start from scratch, the system used was based on current knowledge of what is required to produce good quality video-based materials. A lecturer's room has been setup with the following equipments so that tutorials can be captured:

1. 3 digital video cameras
2. 1 MIMIO (see reference) electronic whiteboard
3. 1 Intel-based and 1 PowerPC-based PCs configured for DV-editing and whiteboard content capture
4. 1 Intel-based PC configured as a streaming video server
5. 1 high quality omni-directional microphone
6. 1 document scanner.

So far, the total cost of the system is under $10,000. While it has less functionality than Classroom2000, it is only one tenth of the cost.

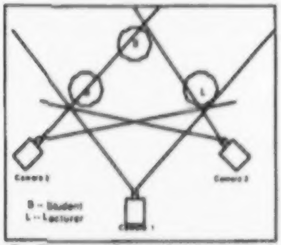

Figure 3: Camera Setup for Lecturer's Room

Problems with Capturing Real Educational Dialogues

Capturing real (as opposed to scripted) educational dialogues presents significant problems in terms of the pedagogic content of the captured material and the task of video-editing.

Pedagogic content

In a small-group discussion (1 lecturer and 2 students), the written materials referred to are often on paper, not on whiteboard as in the materials in the Dissemination System (see reference). Students bring their work on paper, and discussions and amendments centre around the pieces of paper on the desktop. Desktop and surrounding cameras did not get a good angle on the content of paper – even at close range both physically and through zooming. It was very difficult or impossible to make out what is being written on the pieces of paper in sufficient detail. Why is the whiteboard not used in this instance? The ReLaTe project (see reference) found that the use of the whiteboard is in the "tutor's domain". Students are reluctant to "expose" their work on the whiteboard and prefer the familiarity of their own paper (Hughes & Sasse 1997). For students, writing on the whiteboard means publishing their work, which they must be prepared to defend. Additionally, unscripted real world dialogues take time to get going – there are often periods of silence when discussion materials or off-topic chats.

Video editing

In order to produce good quality material, captured tutorial sessions need to be edited. Off-line editing of captured dialogue is the most time consuming task in the process of creating CSVL. It was necessary to first listen to a 5 or 6 second segment of a clip to determine which camera angle to use, then repeat this process until the end of the clip is reached. This "stop-go" approach is very time-consuming and not practical for a lecturer to do. TV studios do real time (live) editing where the producer or director makes the decision to "switch" cameras while the production continues to roll. This "studio" style of creating the final production would be much easier and less time-consuming for the lecturer. However, an individual educator cannot afford dedicated staff to support each captured session.

Implication for Design

This section presents the conclusions derived from the pilot study and the two case studies in terms of what educational users need and what tools are required to provide sufficient support for producing video-based educational materials.

So, what constitute the "ideal" video-based vicarious learning material? Together with the previous findings from the literature and the case studies conducted, the following attributes have be derived:

1. The size of the video should be at least 360x288 pixels (1/2 DV) in a 1024x768 screen resolution.
2. The audio should be captured at 16-bits stereo audio ,sampled at 48kHz.
3. Maintain audio-video synchrony.

However, these attributes are often dictated by the bandwidth that is available while viewing the material online and therefore will be more of a design constraint rather than a design feature. In contrast, the following features can be incorporated irrespective of bandwidth size:

4. Cuts and scene changes can be controlled and incorporated by design into productions.
5. Cuts or scene changes should be used to create structure within the production as well as keeping the viewer's attention at the appropriate level – more than one camera will be required and each camera will need to be placed in the appropriate position to obtain the best possible angle
6. The video must incorporate camera angles that give the viewer sufficient access to props.
7. Allow the viewer to navigate through the video with respect to a clear pedagogic framework.

Derived system requirements

A system that efficiently supports production of video-based educational multimedia must enable the author to create materials with the greatest degree of quality while minimizing the amount of time and effort required to create those materials, i.e., it must be pactical to use.

A survey of the current range of video-editing suites reveals that there are no packages that efficiently support, in terms of time and effort required, the task of authoring in-house video-based educational multimedia. Apple's iMovie is very easy to use but does not support the ability to have more than one synchronized camera angle to choose from at any one moment.

While Adobe Premiere and Apple's Final Cut Pro support multiple camera angles, they do not allow the author to choose camera angles "studio" style in post-production. Both packages force the user to use the "stop-go" approach to video editing. A system is required that can:

1. simultaneously capture DV footage from more than one camera
2. play each captured camera angle (video file) at the same time (once they've all been downloaded and synchronized) so that the author can see exactly what each camera has captured
3. allow the author to choose which camera to use in real-time without having to stop the videos being played (as if the production is being made live in a studio). This task should be as simple as clicking on the camera angle that is wanted at that time to switch to that camera in the final production.

This will critically improve the usability of video-editing systems in three major ways:

1. The pre-editing time will be cut substantially if footages from different cameras can be downloaded in parallel.
2. The editing time will be cut substantially compared with the "stop-go" approach.
3. The editing task and user-interface will be simplified to just picking which camera is "live" or active at certain time.

Conclusions

It is possible to bring the benefits of vicarious learning to individual educators but there are some significant problems and issues that still need to be addressed in order to implement the most effective support for such method of learning and teaching. Producing video-based educational multimedia is more than just pointing a video camera and shooting. Empirical works reported in this paper support the notion that perceived quality of production is significantly affected by the number of camera angles that are used in the production. While the current range of video-editing software packages have the features to produce video-based educational multimedia material of sufficient quality, the tasks in which they demand the user to go through in order to produce such materials are not compatible with the way the lecturer actually needs to work. To make video-editing packages usable in the educational context, the editing task needs to be both quicker and easier. As the number of camera angles in production affects the perceived quality of that production, packages need to support the use of multiple camera angles in productions without forcing the user into a "stop-go" style of interaction to edit videos – this is currently a significant usability bottleneck for users of these packages.

There is currently no large-scale empirical data on how students interact with vicarious learning materials. More importantly, there are no data on how the interaction pattern is affected when there are pedagogic shortfalls resulting from production problems, e.g., missing out vital contents through using insufficient camera angles. These variables are independent from the usual variables investigated in video technology, such as bandwidth, resolution and synchronization. This needs to be thoroughly investigated as pedagogic effectiveness is at stake.

Abstract: It is well established that WWW-based courseware must not restrict itself to the mere delivery of instructional material, but must be grounded in some sound model of instruction and learning. This paper discusses one such model, based on the best of instructional design principles and tries to overcome two of the most serious problems that are being faced in the process of introducing interactive web-based learning, namely disorientation and cognitive overload. Whereas the emphasis in a lot of recent work has been on digital technology reuse, our emphasis is on core aspects of the content development process. Our principal contribution is an intuitively clear iconic notation that can be used to templatize and thus simplify the task of educational content development. We briefly describe the evolution of this model, the experimental effort to evaluate this model and the courseware development process that was adopted.

Present Web-based Learning Scenario

Traditional learning is premised on linear learning, while current brain research finds that learning is nonlinear and relates to interrelations of feedback loops in a holonistic total[Muhammad, 2000]. The World Wide Web can make nonlinear learning much easier than textbook/traditional curricula. Thus web-based learning is widely acclaimed to bring in student-centric, self-paced instruction. However, many of the courses offered on-line and much of the course material that is on-line do not cater to these adjectives. Typically, courseware development is done by translating an existing lecture format course into an HTML document. The traditional learning model, which is predominantly instructor centric, is followed, albeit with far too many inter-linkages (hyperlinks) in the content. There is no real structuring or freedom for the students to choose their path meaningfully. One serious problem in learning that arises due to such ad-hoc non-linearity in content is that of disorientation. It refers to users not knowing where they are, where they have been, or how to get to where they want to go in hypermedia space. This results in a learner picking up disjointed knowledge with many gaps and often wasted energy in duplicate learning [Murray *et al*, 2000].

Another serious problem is that of cognitive overload [Murray *et al*, 2000]. This refers to learners being overwhelmed or confused by the options available to them in multi-path, multi-tool environments such as those provided by hypermedia courseware. This is primarily due to discontinuous narrative caused by breaks in didactic or dialogical flow of the matter itself and improper conceptual flow of ideas or concepts.

Learning object, a digital resource that supports learning, is the current instructional technology leader designed to address the above problems [Wiley, 2000, Longmire, 2000]. However it seems unfortunate that commercial considerations have forced premature focus on maximizing reusability, adaptability, rapid-prototyping, scalability and other such mass production aspects, peripheral to the core goal of learning itself [Greenberg, 2000].

Requirements of a Web Learning Environment

Ausubel maintained and subsequent researchers [French, 1999] have strongly supported that the most important factor in what one learns is often what one knows. Interactive web-based learning, one in which the learner is treated as a co-discoverer of knowledge and asked to work collaboratively, has the potential to capitalize on an adult learner's prior knowledge and experience in a way that traditional approaches have often failed to do.

Thus any web based learning environment must promote:

1. Integrative knowledge building, in a sense that recognizes the learner's existing knowledge base and links to it the new knowledge components as the learning progresses.
2. Customization, which, at the least, offers to a learner choices of meaningful learning paths, styles and pace of learning. A technologically advanced model can also include learner profile (or even build learner profile as learner progresses in her learning) and offer appropriate options, most suited to the profile.
3. Interactive content delivery that engages students continuously. A good environment should also have the facility to establish a contact with peer learners and the facilitator / teacher.

Instructional Design (ID) Principles - as applicable to web based instructions

Given the two serious problems described above, we propose a six-step approach for instructional content development adopting the best of instruction design principles:

1. Define a semantically meaningful unit of instruction – we will call it Concept.
2. Design an appropriate structure of concepts, which connect them in a logical way to ensure that the body of knowledge evolves as the learner progresses with the learning. We can adopt a tool like a Concept Graph for this purpose.
3. Design the right level of granularity of concepts.
4. Define a classification for the concepts.
5. Determine learning levels.
6. Select the right learning primitives to provide the desired learning experiences.

We shall discuss these in some more detail below.

Smaller and semantically meaningful unit of instruction: It is well established that the unit of a typical lecture/chapter, covering a fairly large chunk of content, cannot be easily related to concepts. It suffers from the disadvantages of long durations, unacceptably long attention spans for self-paced learning, and also from the fact that testing for understanding can be done only at unit boundaries [Joyce and Weil, 1996]. Hence educationists and early work in ITS have proposed a smaller unit of instruction. We will denote this by the term concept, a notion we largely base on Bloom's model for Mastery Learning. "A concept is a semantically meaningful unit of instruction with a specific intent type and a matching instruction and evaluation type." [Bloom, 1956]

Concept Graph: This is a simple structure representing prerequisite relationships amongst concepts [Cauano *et al*, 2000].

Granularity of Concept: A concept must have a simple, short and clearly stated learning objective. Enforcing this during review and evaluation will help ensure the right granularity for a subject. Finer granularity provides greater opportunities for learner control. [Quinn, 2000]

Classification of Concepts: Apart from specific intent type, the notion of concept has the other aspect of matching instruction and evaluation type. Content defined for learning a concept should match its intent. The idea is that, a learner, having decided upon the learning goals, can choose a matching type of instruction unit. This leads to concept classification-based on Merrill's work [Merrill, 1999].

1. Facts / Part-Of: Concepts in this category match the instructional objective concerned with the "WHAT?" aspect. Concepts consist of arbitrary pieces of information. Examples are facts about a particular event like a sports match, a particular object like a modem, a mouse, etc.
    i. Kind-Of: Here we are concerned with the classification aspect of the knowledge to be learned, identifying relevant examples and non-examples. Examples are categorizing various animals into different species, categorizing natural phenomenon, etc.
2. Rule-Using/Procedural: In these, the instructional objective is concerned with "HOW" to do some thing. A procedure is an ordered sequence of steps for accomplishing some goal. Examples of such concepts are adding fractions, operating a machine, sending e-mail, etc.
3. Principle/Problem solving: This category is concerned with prediction and explanation of "WHY" things happen in the world. They are cause-and-effect, correctional, or constraint relationships. A principle is a relation between two or more changes. Such concepts will have the problem-solving aspect as their main objective. Examples of such concepts will be "an increase in price causes decrease in demand", "plants grow from a seed to a seedling to a plant", etc.

Since this classification basically focuses on the intended objective of learning units, one significant outcome is that the environment can be designed to adopt pedagogically correct behavior appropriate to a learner's choice of learning unit type. For example 'Part-of ' type learning can occur if information is communicated in a form that remains accessible to the learner, say, a list of directions, throughout an act of learning [Gagne *et al*, 1992]

Learning levels: The issue of depth of learning or performance level leads to identification of learning levels as follows:

1. Memorize: Performance at this level merely requires the learner to search memory in order to reproduce or recognize information presented.
2. Understand: This level requires the learner to identify the examples and non-examples and their attributes in order to categorize and classify the data presented. Performance at this level promotes comprehension.
3. Apply/Use: This requires that the learner be able to apply the knowledge within a context, where it is clear that the piece of knowledge is applicable.
4. Problem-Solve: This requires the deepest level of assimilation. This level requires that the learners recognize if and when a piece of knowledge is applicable, and then apply it correctly.

Theoretically any concept type can be learned at any learning level.

Learning primitives: Learning a concept is a collection of several types of learning experiences such as reading/listening to instructions, exploring the subject matter, solving problems and many more. In a teacher centric environment a well designed and delivered lesson takes care of all these aspects. But in a learner centric environment the system has to provide these experiences explicitly by the means of various learning resources. We visualize these resources as building blocks enabling a learner to build her knowledge for a concept and term them as learning primitives, somewhat similar to Cisco's RIOs [Cisco, 1999]. Each learning primitive gives the learner a suitable learning experience (at required time, of suitable knowledge type, at required learning level and in desirable media type). Various learning primitives [Gharpure & Mudur, 2000] have been identified and these can be assembled into a concept. These include statement of objective, entry test, instruction, demonstration, simulation etc. More can be thought of. A primitive's contents are developed as a combination of interactive media elements and presented depending upon domain, environmental capabilities and learner preference.

Thus a model can now be evolved based on the ID principles as discussed above.

Learning Unit Class Model

A Learning Unit Class (LUC)[1] is the collection of learning primitives required to deliver learning of a particular concept for a combination of learning level and knowledge type. Content for any subject is a directed graph of LUC nodes, where arcs denote pre-requisite knowledge. The arcs could move across different subject matters. We have designed an intuitively simple iconic notation for different LUCs, which are shown in Table 1.

---

[1] In order to avoid any possible confusion/patent/copyright infringement, we have intentionally moved away from using already in-use terms like reusable learning object, knowledge object, educational object etc. for this or reusable information object for learning primitives. It also helps us emphasize the fact that our focus is on the creation of the content. Further

As an example, for teaching a procedural concept at the level of application, a demonstration will be very useful, while for teaching the same at the level of problem solving, an interactive simulation might work much better. Thus for each of learning unit class a template[2] (as a set of primitives) can be generated (*cf* Fig. 1 for an example). The real challenge before an instructional designer now becomes that of identifying suitable concepts, their learning levels, specification/design of various learning primitives for communicating the concept and finally the concepts into seamless and logical flow content.

CONCEPT LEVEL — TYPE	MEMORIZE	UNDERSTAND	APPLY	PROBLEM SOLVE
PART-OF /FACT OBJECTIVE—	 Recall or state fact	 Recognize/Identify fact	 Use/apply fact in carrying out task	 Identify required fact and use/apply in task
KIND-OF CLASSIFICATION OBJECTIVE—	 Recall examples / non-examples	 Recognize example / non-example;	 Use correct example.	 Identify example in current context and use
PROCEDURE OBJECTIVE—	 Recall rule / procedure	 Select / identify the appropriate procedure	 Use/apply a procedure/skill	 Trouble shoot, adapt variant to solve problem
PRINCIPLE OBJECTIVE—	 Recall principle	 Identify scenario in which principle is applicable	 Apply the principle in a known scenario	 Identify and Apply the principle in an unknown scenario

Table 1: Iconic Notation for LUCs

---

these could be suitably wrapped into standard reusable learning components, whenever such technological packaging is demanded.

[2] Because of support for definition of such templates, this model has the scope to be developed as an integrated environment for content creator, offering a matching toolset for each template to create course content based on ID principles.

LUC TYPE	OBJECTIVE	ENTRY TEST	INSTRUCTION	ILLUSTRATION	DEMONSTRATION	EXPLAINATION	EXPLORATION	SIMULATION	EXAMPLE	NONEXAMPLE	REMINDER	REFERENCE	EXERCISE	HINT	EVALUATION	WORKPLACE	ADDRESS BOOK	ASK QUESTION	FEEDBACK
666	R	R	R	R	R	R	O	O	O	O	R	R	R	R	R	R	R	R	R

Figure 1: A template for a Learning Unit Class (type: procedure, level: apply)

The Experiment and the Process Adopted

This experiment, conducted by one of the authors, Professor Prachi Gharpure involved developing the web-based content for a course titled 'Introduction To Internet ', paper IV for MECTA (Master of Education with Computer Application), a post graduate degree program at SNDT University, Mumbai. The content covered the entire syllabus for the course, as defined by the SNDT University. The course is being taken by MECTA students as we write this paper and the results of an on-going evaluation of the content will be available for further study by June 2002. For review purposes, part of this course is temporarily uploaded on http://www.sndt.netfirms.com/Faculties/Education/DET/Online%20Learn.html. The model-based process adopted is briefly presented in Table 2.

Phase	To be Executed By	Tasks
I May alternate with phase 2 in the process.	- Content Expert - Instructional Designer	1. Identify concepts covering syllabus 2. Map concepts into graph with pre-requisite links[Tellis, 2001]. Fig. 2 shows a first level graph whose nodes get exploded as the learning progresses. 3. Define LUC consisting of learning primitives (guided by template) most suited to meet the learning objectives of the concept. Fig. 3 shows the screen shot for one such LUC
		Example Tools: concept graph editors such as http://www.inspiration.com/ http://users.edte.utwente.nl/lanzing/cm_home.htm
II May alternate with phase 2 in the process.	- Instructional Designer - Software Developer - Visual Designer	Development of templates for different LUCs.
		Example Tools: Spreadsheet, Presentation, Word Processor, etc. (This step in the process adds value to the creation process in terms of consistent layout and look and feel throughout the learning experience. This is very important because the learner can navigate smoothly as she develops a certain amount of familiarity and comfort level in navigation, interaction and knowledge assimilation processes.)
III	- Instructional Designer - Visual Designer - Software Developer	Creation of interactive content
		Example Tools: Web content authoring/publishing tools that enable creation and integration of various components. (This step in the process is the actual content creation process .The process should consider issues like Learner control, Media selection, Interface Consistency, Internet issues etc.)
IV	- Software Developer	Integration into courseware and web based education delivery environment
		Example Tools: E-Learning Management Systems, for an overview of such systems http://www.ncst.ernet.in/~vidyakash/portal/tools.shtml
V	- Content Expert - Instructional Designer - Learners from a representative community	Courseware review Specification of Evaluation criterion
		Example Tools: Web-based feedback forms, statistical analysis tools etc.

Table 2: Model based process for courseware development

Conclusion

A model driven content development process, rooted in instructional design, offers excellent scope for developing an integrated system that guides courseware developers through templates to create potentially high quality content for individualized learning. The principal contribution of this paper is one such model, with an intuitively simple iconic notation. The model has been tested by actually creating content for a postgraduate course which is presently live. The content evaluation phase is currently on for evaluating the results for this model driven process both from instructional design and from learner perspectives.

Digital Lecture Halls Keep Teachers in the Mood and Learners in the Loop

Abstract: In the transition from traditional teaching and learning to eLearning, we advocate avoiding disruptive approaches. We claim that many virtual university and corporate university efforts worldwide try to showcase big leaps forward yet lack sustainability, suffer from in-vitro conditions, and leave behind the big mass of teachers. Our Digital Lecture Halls (DLH) project accommodates traditional teaching and learning styles, making them *digitally* available for computer assistance. It also reaches out to a large variety of computer-assisted methods and to accompanying new organizational and business models. Apart from this non-disruptive approach, DLH also focuses on large venues. In contrast to known *electronic classroom* efforts that are limited to about 25 local participants, audiences without size limits are supported in DLH. The first implementations support 150 and 1000 participants. The paper describes the general DLH approach and architecture as well as details of the learners-in-the-loop components.

Rationale

Despite great achievements demonstrated at AACE conferences and in *in-vitro* showcases, computer-assistance is not common in lecture halls and classrooms, except maybe for the replacement of overhead transparencies by beamers. In cases where computer-assistance has become a commodity, like at *Hi-Tech* companies, sophistication is rather low: Computer Based Training (CBT) and Web Based Training (WBT) resemble behaviorist computer assisted instructions of the mid sixties, tele-teaching lessons present only a peep show like view for remote spectators, and *virtual universities*, behind a shiny *welcome screen* facade, offer mostly on-line versions of lecture notes originally conceived as paper documents.

One might argue that continuous and tertiary education worldwide is currently faced with a race towards corporate and virtual universities. Politicians and managers seem to be delighted with the budget-relieving vision of virtual teachers that can be replicated by way of keystrokes. However, looking at the continuation of many virtual university start-ups founded out of traditional university structures reveals some basic problems. The development efforts for suitable course material are tremendous for the virtual university set-up. Further, educators accustomed to on-site lecturing and contact to their students must realize that in distance education they face a different relationship with their students, requiring a different teaching and tutoring style to achieve success. As a consequence, we propose to avoid leapfrogging from real to virtual universities. Rather, we suggest a smooth transition that starts with the current and well-understood real universities. By augmenting current teaching venues with new technology, these teaching venues become digital (*electronic*) classrooms, Digital Lecture Halls (DLH), and virtual laboratories. Among these three, the present paper concentrates on Digital Lecture Halls since both electronic classrooms and virtual laboratories on the Internet are investigated in other projects. To the knowledge of the authors, no project concerning Digital Lecture Halls and e-classrooms, has addressed venues of large size, i.e. lecture halls for hundreds of learners.

Apart from addressing a new level of venue size, our approach is also novel as it is non-disruptive. The move from *analog* to *digital* teaching imposes as little as possible an adaptation for both teacher and learner in terms of teaching and learning methods and styles. Hence, the digital lecture halls proposed here remain physical venues -- distribution and virtuality is not an immediate goal. They even accommodate teachers who want to continue scribbling proofs or discourses by chalk and who are used to filling an entire handful of subsequent blackboards with a single proof or discourse. Finally, they offer *after hours* availability of such traditional lectures as a first noticeable improvement over traditional teaching and learning models. We will show that making this 'hardly noticeable' analog-to-digital move requires considerable yet feasible investment. The return on investment is unprecedented: instead of addressing only small elites of teachers, we emphasize changes for the masses.

One may ask whether a 'hardly noticeable' change is worth the effort in the first place. The answer is twofold: it is only the border of a continuous spectrum and being so simple, it can reach the masses instead of the elite. The remainder of this paper will show that the DLH concept accommodates all types of teaching methods: synchronous and asynchronous, local and distributed, strongly guided up to open explorative teaching methods. The difference is that by setting the entry threshold low for ordinary teachers, we intend to motivate nearly all teachers to enter the digital era. Also, the variety of computer-assisted teaching methods can be introduced at an individual pace and based on the experiences gained along the road – a policy which we claim to be indispensable, if the fast-moving computer and networking technology and the slower-moving *teaching culture* (pedagogy, didactics, and instructional sciences) are to be synchronized. By gradually adapting pedagogic and didactic concepts to the improved possibilities, the evolution process can keep pace with urgently needed feedback and evaluation. Such a smooth transition may include the following intermediate steps, each of which represents a computer-aided teaching set-up in its own rights:

1. DigiMax: Computer-augmented frontal teaching is immediately available in the digital venues (same-time / same-place), providing a *digital audimax* (DigiMax) setting in the DLH.

2. LearnerLoop: Cooperative learning can be introduced by offering mobile computing solutions for the learners in the audience owning portable devices.

3. AfterHours: Asynchronous rehearsal is the first immediate gain if streaming servers are added and lectures are kept on-line for a reasonable time.

4. NetExL: by hooking the digital venue onto the Internet in synchronous live mode, both remote humans (for example guest expert teachers) and remote bits (data such as Web sites, code such as simulations, virtual Internet labs, etc.) become available. Distributed DLHs can be created by mirroring the digital venue, allowing distributed classes to take courses. As streaming and multicast support are added, individual distance learners may join in.

5. CourseLine: Taking different kinds of recordings (see below) as raw material, the AfterHours level of different-time/different-place learning can be extended: Raw material can be post-authored into valuable course material for rehearsal and/or self-paced learning.

These steps are realized as different yet integrated components of the DLH hardware/software, each in turn consisting of several subcomponents. The detailed description of the steps will form the rest of the paper.

The Digital Lecture Hall

This section describes the design and implementation of the Darmstadt Digital Lecture Halls. The description follows the possible evolutionary steps, and hence, the above-mentioned components, that lead smoothly from *traditional teaching going digital* to different kinds of Internet/computer-assisted teaching. In Figure 1, these steps are related to a taxonomy of computer-supported cooperative learning (CSCL), showing that DLH covers all relevant areas of CSCL.

A coarse architectural description of DLH is depicted in Figure 2. It shows three basic layers of DLH, namely, hardware, components, and content (course material). The description will be extended only in the context of corresponding software functions. Among these, DigiMax is not only the first step of DLH's use, it is also the glue for further components. In particular, most LearnerLoop functions are directly related to DigiMax subcomponents, and AfterHours is an extension of DigiMax for recording. NetExL extends the reach of DigiMax over the network and CourseLine accesses all other components. Figure 2 also depicts a learner management system (LMS) (Hornung & Hornung 1999). Core LMS functions like network access and group support during a lecture are realized as part of the project. Additional LMS functions are external to the DLH project. DLH is prepared for integration with an external LMS.

The next four sections follow the stepwise approach of DLH components and provide more details about the respective subcomponents and functionality.

Figure 2. (right) Coarse DLH architecture

DigiMax: Traditional Teaching Goes Digital

DigiMax realizes those computer-assisted features of a large-size auditorium that are related to the tasks of the lecturer. Therefore, minimal task change and minimal cognitive overhead are the key requirements for lecturers making the *analog-to-digital move*. Lecturers already accustomed to computer-based teaching, on the other hand, should find maximum support for their advanced needs. DigiMax consists of several software modules and supports flexible orchestration of numerous electronic lecture appliances and general-purpose hardware local to a lecture hall.

Virtual Multi Board: From the instructors' point of view, the main software module is the Virtual Multi Board (VMB). It is the only visible interface to other subcomponents like ScreenRecorder, RoomControl or LocalLectureLoop Applications.

Yet the VMB is not only a control interface. Major features are inspired from traditional *analog* use of lecture halls – following the major DLH goal to assimilate analog forms as much as possible. In traditionally large audiences, lecturers will not use a single blackboard. For instance, university lecturers teaching mathematics consume a handful of blackboards for a single proof. These multiple blackboards are usually visible to the audience at the same time. Even for a more loose related series of blackboards, it is a key feature of the *teaching technology* that several blackboards *in the history* remain visible: both to quickly review this history (to considerably improve retention rates) or as a buffer mechanism when learners lag behind with their note taking or re-reading. In order to support this *teaching technology* on the digital side, the VMB can be configured to hold threads of blackboards from *history*, manage multiple threads in parallel and display them with a customizable layout on a seamless multi screen display provided by the DigiMax hardware (Figure 3). Part of the VMB display space may also be configured to hold the output of any other software such as the NetExL component which might project a remote expert, lab, or peer DLH or results from quizzes deployed with the LearnerLoop Assignment module.

VMB offers simultaneous use of multiple input stations. Our initial DigiMax hardware provides two stations: a whiteboard and a tablet. The 72" whiteboard is rear-projected and mounted in such a way that the auditory has maximum visibility and the lecturer has easy access. The pen-based inductive tablet with rear display is positioned like an *analog* overhead projector. Using the tablet, the lecturer can more easily keep eye contact with the audience – a feature considered crucial by many teachers today and a main reason for many to move from blackboards to overhead projectors. Both stations can show the same or different presentation threads or show a composite view of threads and controls and other applications not meant for presentation to the auditorium, like online feedback captured with our local loop tools, presentation control and notes or room control.

ScreenRecorder: Many tele-teaching settings feature *electronic whiteboard software* that integrates recording functionality. Annotations made by the lecturer are recorded and can be played back during (asynchronous) rehearsal. Advanced settings also support slide presentations but require the presentations to be converted to an intermediate format, losing features of the native presentation system, for example animations in PowerPoint (see Lecturnity [www.lecturnity.de]). In our approach, recording is supported for arbitrary software. We can create snapshots as well as stream screen recordings at high frame rates. We can capture the live application, arbitrary animations, dynamically created output as well as output from remote software. Audio output is also captured. The snapshots are used by the VMB history functionality. The stream recordings are targeted for AfterHours and for ToGather, a tool part of the LearnerLoop.

BEST COPY AVAILABLE

Our annotation library supports ink as well as higher-level objects such as pointers, text and simple geometrics. We provide necessary bindings to make VMB and ScreenRecorder aware of underlying features of the attached appliances and the running presentation software. Different whiteboard input tools switch between annotation modes. Slide changes or animation steps in applications like PowerPoint signal events in ScreenRecorder to create dynamic index frames and snapshots. The slides text is exported on the fly and used for further indexing. We provide a COM and Java Library for integrators to make their applications aware to our system.

The DigiMax Software layer is flexible regarding the underlying hardware. Although the complete software can be installed on a laptop, we recommend using a stationary installation in a lecture hall, consisting of at least a dual-screen projection, rear-display tablet and a server holding core services and the presentation system.

Our initial DLH prototype in a Lecture Hall fitting 150 students has the two input stations described before and uses a 9x2.25m multi-screen projection with three projectors totaling a resolution of 3840x768 pixels. A Windows 2000 Server with an AGP- and an additional Quad-PCI-Graphics Card is used as the central server that drives all attached displays at once.

Currently, we are preparing a mobile DigiMax extension unit to be used for DigiMax enhanced lectures in a legacy lecture hall fitting 1000 students. We will augment the existing XGA projection with a digital sideboard of two stacked projectors and use a rear-display tablet as input station. The mobile unit will also hold hardware in use by other DLH Components.

Lecturers who need or want to use their own equipment (for example a laptop with a computer-specific license of software to be shown) can use a stand-alone version of ScreenRecorder on their computer to generate processable content for a stationary DigiMax and may use a web based interface to remotely access VMB functionalities.

LearnerLoop: integrating local learners

A major goal in DLH is the tight integration of learners into the digital teaching/learning process. This has been a goal in other projects as well, be it tele-teaching setups or electronic classrooms. DLH again emphasizes a smooth evolution and large venues in this context.

Tele-teaching setups usually support audio connections to learners for question-and-answer phases of the lecture. In this respect, the multiple pen-tilt-zoom (PTZ) cameras installed in DLH as well as the microphone / speaker installation – all described in the context of AfterHours and NetExL below – already provide a level of sophistication that goes beyond common approaches.

Ambitious electronic classroom projects have equipped learner workplaces with computers carefully designed for integration in the computer-assisted teaching process. Computer-equipped learner workplaces are central to DLH, but with three major differences:

Computer-equipped learner workplaces are supported and recommended, but not mandatory. Use of video/audio communication is offered as an alternative.

Our experience with the *Classroom-of-the-Future* in Linz (Mühlhäuser 1996) shows that computer-equipped learner workplaces may lead to learner distraction and social and cognitive disintegration of the class.

Quite often, the individual access and high degree of freedom provided by typical per-workplace user interfaces, together with the cognitive overhead and level of concentration required by that user interface, leads to a large number of individual *learning threads* among the students in class. For CSCW software and group meeting rooms, this observation (and other similar ones) has led to the recommendation to even avoid per-workplace computers. In our case, it has led to the *minimal distraction* requirement that materializes in the TVremote subcomponent of LearnerLoop described below.

In our vision of virtually every lecture hall of a university or organization being DLH-like, we imagine learners to come and go and to switch venues quite often. Given the high level of deployment of mobile computing equipment among today's and tomorrow's learners, it seems quite natural to support learner-owned equipment. This assumption has far-reaching consequences that set DLH apart from electronic classrooms. Four categories of learner devices are considered and reach from SmartPhones via PDAs and pen-based notebooks to laptops. Wireless connectivity is the only feasible connectivity approach (this approach scales up to an online campus vision where learners can access all kinds of resources on the move). The LearnerLoop has to accommodate with a broad performance range with respect to both the learner device and the communication bandwidth.

Regarding the hardware, the four device classes envisioned were mentioned above; the wireless networks currently supported are General Packet Radio Service (GPRS) and IEEE 802.11b wireless LAN (wLAN), to be complemented by a Personal Area Network (PAN) standard in the future. The LearnerLoop component comprises the four major subcomponents TVremote, Assignment, ToGather and UpLoad, which we will now describe in turn.

TVremote: As the name suggests, TVremote provides minimal functionality for the learner to *control* the digital lecture taking place. Following the minimal distraction requirement, the functions are usually mapped onto soft keys of the device, so that *pressing a single key* suffices for operation. The main function of TVremote is *tagging*: by pressing a tag key on the device, a learner expresses particular interest in the current phase of the lecture. She may either mark the beginning and end of a relevant section or indicate interest in *what the lecturer just said / presented*. In the latter case, the marker is set slightly back in time. Technically speaking, such tagging results in an entry in the learner's personal annotation file which points at the audio/video/presentation recording (see AfterHours) centrally stored. In a future version of DLH, tagging will influence the *aging* process of the recording, depending for example on whether or not a learner copied the marked parts to her private workspace.

Another important TVremote function is *RaiseHand*, a function that queues the learner for question. The lecturer may (immediately or later) call upon the learner using corresponding DigiMax functions. In the latter case, DigiMax calls VMB to display the slide that was visible at the time of *hand-raising*. While hand-raising is supposed to lead to immediate reaction by the lecturer for smaller audiences and local-only lectures, delayed calling-upon for questions is assumed to be common for very large audiences and distributed lectures.

We also use TVremote to implement a simple on the fly evaluation function, where the students can indicate if the instructor is doing a good job concerning understandability and presentation speed.

Assignment: The Assignment subcomponent offers a standardized means for lecture-initiated interaction, task assignment, and exams. Questionnaires, assignments etc. are modeled by the system as computer-based forms. Customizing this model, the lecturer can employ online questionnaires and examinations during the lecture. These questionnaires can be simple yes/no questions or more complicated multiple choice, gap text, or free text question / answer forms. The lecturer may perform the evaluation right on the spot, defer it to a later time or delegate the work to tutors. Questionnaire access can be anonymous to facilitate participation of learners who are scared of contradicting the lecturer. Exams, on the other hand, are of course authenticated. A tamper-proof authentication for official exams is still under development with our IT security research group.

ToGather: For a higher level of learner involvement and for group work during lectures, we relax the *minimal distraction* requirement in the context of the ToGather subcomponent. This subcomponent targets laptops, pen-based computers and hybrids used by learners in the DLH. Learners have the possibility to form closed discussion groups to perform group annotation. Their devices receive a live stream from the lecturer's input, presentation and annotations via ScreenRecorder. Learners can annotate this stream and see the annotations of other group members. Since local storage can be limited or is often not properly secure (in terms of backup), annotations are also stored on a central server. The learner can recall his notes offline from his computer, for example on his way home in public transport. She can exchange her notes between other students, ad hoc between devices. If willing, she may also expose her notes over the AfterHours system.

UpLoad: To prevent misuse of the network infrastructure, DLH is equipped with a firewall, which is part of the DLH specific LMS and allows access to be configured to the exact needs of different lectures. In this context, the Upload component provides learners with the possibility to access third-party virtual lab software during the lecture, based on access rights granted by the lecturer. This mode of operation is only possible if the wireless network infrastructure is not a shared installation, for example a shared campus-wide network.

TVremote and Assignment: the underlying OCLI platform

TVremote and Assignment use a common architecture, called Open Client Lecture Interaction (OCLI) (Trompler et al. 2002) and one generic model, called eQuestionnaire (eQ). OCLI supports instructor-based definition, control, and assessment of eQuestionnaires, and learner-based filling-in and submission. eQ embraces a broad spectrum from personal highlighting, over voting to assignments distributed during or after lectures.

OCLI uses a web-based XML processing framework and supports learners with any wireless networked terminal device capable of running some sort of web browser. Devices currently in use are WAP phones, PDAs like PocketPCs and notebooks. The OCLI system can be accessed by web applications, too. ToGather integrates OCLI access into its user interface. OCLI consists of five major modules: ADMIN, CTRL, DISPLAY, CORRECT and SCORE.

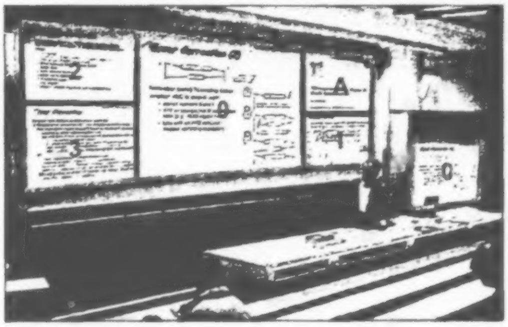
ADMIN, the administrative component, is intended for instructor use before the lecture. Featuring hierarchical curriculum/lecture/lesson structures, it lets the instructor define eQuestionnaires based on a set of pre-defined set of eQ-types (such as timestamp markers, Q&A, assignments, polls) and of answer types (such as multiple choice, free text, selection).

CTRL, the control component, is again mainly intended for instructor use. This component determines the dissemination and accessibility of eQs with respect to both the time period of availability and the authorized audience. For Q&A sessions, CTRL supports the instructor in queuing, displaying, calling-upon, and answering questions during the lecture.

DISPLAY is the display component. This module assures the translation of generic XML-based eQ definitions into terminal device specific formats (Figure 4). It provides the user interface to the learners. Learners may choose between an anonymous or authenticated mode, depending on the lecture's policy.

CORRECT takes over the assessment, evaluation, and correction of learner input to instructor-initiated eQs (such as assignments, polls, or exams). For self-assessment purposes, instructors can call upon the automatic correction features of CORRECT. For other cases, the module presents the learners' eQ replies to the instructor, supports their correction and optional annotations, and conveys the assessments back to the learners.

SCORE adds statistical and graphical evaluation for sets of filled-in eQs. These may be viewed by the instructor or the learners on their terminal device or viewed on the VMB.



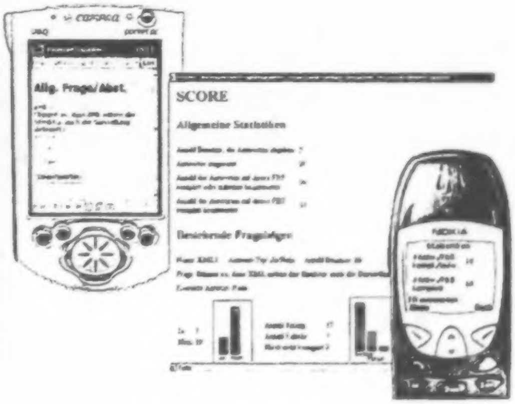


Figure 3. (left) Augmented photograph of DigiMax with VMB (0,1,2,3: thread with history, A: 2nd thread)
Figure 4. (right) OCLI: Assignment on different devices

AfterHours

AfterHours resembles the well-known lecture recording features for recalling the lecture after the sessions and before tests. This feature is found in many other distance learning and virtual university projects with a vast amount of tools available today. AfterHours approaches several issues we found especially important: Firstly, Multi Perspective Video, following observations first published by Jain and used in his MPIvideo products (Jain 1995). In contrast to common practice for tele-teaching, Jain advocates the use of multiple cameras. He refers to the cognitive process by which humans settle in an environment by subconsciously taking *snapshots* from different perspectives and view angles. Our current setups use two instructor and two audience cameras.

Secondly, automatic camera control and video composition, leveraging off an approach described in (Rui 2001). This eliminates the necessity of an assistant in charge of handling the multiple video streams and cameras.

Thirdly, we include student observations during and after recording to create a dynamic media repository. Students using TVremote to tag the lecture during the session can download compiled streams of the lecture containing only sections of interest. Tagging results can be shared in the same way as ToGather lecture notes. They are used for indexing and can be accessed together with the video and presentation recordings. A post-recording comment system is under development. Server access statistics and tagging results are used to garbage collect unused sections of the recordings.

BEST COPY AVAILABLE

NetExL and CourseLine

Since the NetExL and CourseLine components exist only in prototype versions, their description will be summarized here with a lesser degree of elaboration.

NetExL is currently realized as an outbound and an inbound subcomponent. The outbound subcomponent makes a live lecture recording available on the network. Corresponding to the available bandwidth of the remote site(s), several quality of service options exist. For high-bandwidth access on campus, the remote site receives all video streams and may interactively control the preferred camera stream. For lower bandwidth, either the main stream or no video stream at all may be selected. The inbound subcomponent places arbitrary inbound streams (camera input from remote experts, remote learners, or remote DLH sites) on a VMB sub-screen and optionally onto learner workplaces. Connections have to be manually set up requiring human intervention. This functionality must be augmented for further versions; for example as the lecturer calls upon learners for Q&A (either following a RaiseHand command or an Assignment based submitted question), she is to be auto-connected to the VMB remote-learner-sub-screen.

Within CourseLine, we explore two paths towards advanced teaching: starting from recorded lectures, furthering the above-mentioned authoring-on-the-fly approach and using the sophisticated DLH venue for a seamless introduction of advanced instructional strategies, like *Algorithm Animation* in computer science education (Rößling & Freisleben 2001).

Related approaches

Related work has been discussed in the course of this paper. A few general comparisons shall be added at this point, comparing DLH to electronic classrooms, virtual universities, and to tele-teaching efforts.

Of course, the project reported here is not the first digital teaching venue ever built. For comparable examples, see (Abowd et al. 1996) (Brown et al. 1998) (Ginsberg & Foster 1998) (Mühlhäuser 1996). However, other such venues were mostly built with only some of the above-mentioned milestones in mind. Even very advanced projects such as *Classroom 2000* at GeorgiaTech or the *Classroom-of-the-Future* project at the Ars Electronica Center in Linz, are restricted to classroom size around 25 participants.

However, some key goals and concepts of these electronic classroom projects are common with those of DLH. As a consequence, tools developed in the context of these projects partially resemble those presented in this paper. As discussed, major differences between electronic classroom tools and DLH tools for synchronous delivery are the interactive presentation support through the advanced possibilities of VMB and the learner integration via the Learner Loop Software.

Virtual universities have been mentioned several times in the present paper. DLH was positioned as an alternative approach in the sense that a smooth path from current to *digital* universities was proposed in contrast to the *leap* into virtual venues. At this point, it should be added that no commonly agreed definition of virtual universities exists and that other terms such as *corporate university* and *virtual campus* are used with overlapping meaning. Some of the corresponding projects concentrate on organizational and management issues, the technical aspects of these are largely addressed by learner management systems like WebCT (www.webct.com). Most virtual university projects offer on-line material for self-paced training - few of them go far beyond on-line versions of the lecture notes and/or classroom teaching material.

Lecture halls have been augmented with networking and computing equipment for tele-teaching. Among the many setups and projects worldwide, only a few are directly related to computer-assisted learning research and development activities like the activities at the Universities of Mannheim and Freiburg (Hilt et al. 2001). The work of these has brought forth a noticeable requirements document contrasting the status and vision of tele-teaching (Hilt & Kuhmünch 1999). This work also includes a description of the major scenarios to be supported, called *remote lecture room*, *remote interactive seminar*, *interactive home learning*, and *individual learning with CBT*. The overlap of these goals and concepts with the DLH project are obvious, yet these projects have different foci, mainly the support of large remote groups via sophisticated multicast and adaptive video, and the furthering of interactive whiteboard software. Such aspects at the core of computer-science related tele-teaching research, are of course relevant for DLH, but not considered the primary focus. Rather, DLH concentrates on issues such as large projection and intuitive (multiple input station based) input, minimal distraction and ease-of-use, and maximum tele-presence – as discussed in more detail above.

In summary, the research domains discussed in this chapter are complementary to DLH in their focus. Although they even have a different world view, all of them can be regarded as steps in the evolutionary process of digital lecturing proposed by DLH.

Lessons learned and summary

Despite the many virtual university and tele-teaching projects worldwide, many issues have yet to be resolved and many leapfrogging attempts may be questioned regarding their sustainability and effect on the *masses*. The Digital Lecture Hall project described takes a stepwise approach and offers an easy start for *the average teacher and learner* with virtually no need for behavioral change and with minimal cognitive overhead. The paper has introduced the major components that support stepwise sophistication, called DigiMax, LearnerLoop, AfterHours, NetExL, and CourseLine. We have shown how major known teaching and learning approaches can be accommodated by DLH.

Prototypes of DLH have been in use since summer 2001. There have been quite a number of concerns that the very low *entry threshold* for lecturers might be a temptation not to change the teaching process at all. These concerns did not turn out to be justified: average lecturers quickly learn to appreciate the additional possibilities offered by a digital environment. They will not switch to a different technology for technology's sake or by curiosity, such as the *elite* gathered in virtual university projects. This supports the basic assumption of DLH: virtual university projects are still too much *in vitro*, and teaching will only change on the large scale in the pace dictated by pedagogic and didactic improvements.

All in one, the first lessons learned strongly support the assumptions made at the outset of the DLH project.

Abstract: The use of the Internet as an instructional tool in higher education is rapidly increasing. However, alongside the enthusiasm and creativity that generally accompany this process, essential questions regarding the learning quality and effectiveness of online courses emerge too. In order to answer these questions a comprehensive research program is currently examining Virtual TAU – a campus-wide project aimed at integrating the Internet into the instruction of Tel-Aviv University's academic courses. In this paper we describe the research framework for the study of Virtual TAU, along with preliminary findings of the various studies at three levels: (a) the *macro level* taken the institutional perspective on the diffusion process of the Internet within instruction on the campus; (b) the *mezzo level* focuses on the character of teaching and learning processes emerging in web-supported courses; and (c) the *micro level* looks at the actual usage of the web in the teaching and learning of specific courses.

Introduction

The use of the Internet as an instructional tool in higher education is rapidly increasing. In the last decade, introduction of this new technology in higher education has generated a rich variety of teaching configurations (AFT, 2001; Bates, 2000; Bonk, Cummings, Hara, Fischler & Lee, 1999; Collis & Moonen, 2001; Harasim, Hiltz, Teles, & Turoff, 1995; Mason, 2000; Mioduser & Nachmias, 2002). These range from the incorporation of web technology into existing face-to-face courses as an additional information support tool, to the development of complete distance learning courses.

To look at the impact of these developments within the context of higher education implies, in fact, to examine the ways they challenge the 2,500 years old Socratic, face-to-face instruction modes characterizing most college and university teaching. However, alongside the enthusiasm and creativity characterizing this process, essential questions regarding the learning quality and effectiveness of online courses emerge (e.g, AFT, 2000; Guri-Rosenblit, 2001; Phipps & Merisotis, 1999). To answer these questions comprehensive research, is currently being conducted into Virtual TAU – a campus-wide project aimed at integrating the Internet into the instruction of Tel-Aviv University's academic courses. In this paper we describe the research framework along with preliminary findings.

The Virtual TAU Project

Tel-Aviv University (TAU) is one of the largest research universities in Israel. Located in the center of the country, it serves about 27,000 students annually. These students are enrolled in about 6,000 courses which are taught by about 4,000 instructors in almost every academic discipline.

The Virtual TAU project at Tel-Aviv University (http://virtual.tau.ac.il) was launched in the academic year 2000/01, in response to a government initiative to prompt advanced learning technologies in Israeli higher education. The project aimed to initiate and catalyze a process by which gradually more faculty members use the Internet to enrich learning processes and to make instruction more efficient and flexible.

The web-shell used by Virtual TAU is *Highlearn*, a novel Internet course management system. Similar to other web-supported course systems (e.g., *Blackboard, WebCT, Lotus Learning Space*), *Highlearn* allows easy creation of an information base for the course content and didactic activities, and supplies both synchronous and asynchronous communication tools for students and instructors. In addition, it provides tools that assist the instructor in administrating the course (e.g., course scheduler, address book).

One of the fundamental principles of the project is that the instructors, most of them TAU faculty, maintain full responsibility for the course's website. Their views regarding the objectives, syllabus, and instructional methods lead the development and the implementation of the course. No pre-designed pedagogical solution are imposed. Rather, each instructor acts according to his or her own pedagogical approach. Most of the projects' activities are aimed at empowering the instructors, helping them in the realization of their pedagogical vision.

The Study OfThe Virtual TAU Project

One major objective of the research design is to evaluate the potential of the web-supported courses and to examine the conditions needed to realize this potential. The research framework of Virtual TAU consists of three levels of analysis. First is the *macro level*, which focuses on the assimilation process of the Internet into the campus instruction from the institutional point of view. Second is the *mezzo level*, which focuses on the character of teaching and learning processes emerging in the web-supported courses. Finally is the *micro level* concerns the characteristics and consequences of the actual usage of the web features for teaching and learning purposes in specific courses. A detailed description of the research framework can be found in Nachmias, 2002.

Macro Level: The Assimilation And Diffusion Process

Questions asked at this level relate to the characteristics of the assimilation and diffusion process of the new technology, and to the factors affecting this processes. Rogers (1995), who contributed a widely accepted conceptual framework for the understanding of diffusion of innovation process, views organizations (e.g., universities) as social systems composed of individuals with varying degrees of openness to technological innovation. The rate at which an innovation is adopted within an organization is a function of certain characteristics of the organization's staff, the innovation itself, and the information disseminated about it. An innovation will be more easily adopted if the potential users are convinced that there is some advantage in using it, and if the innovation is compatible with their current needs and values.

The major research questions asked at the macro level are: Does the diffusion of the Internet in the TAU campus follow Rogers' model? What is the profile of the Tel-Aviv University staff members who have adopted the Internet in their academic instruction? What are the factors (e.g., central support, staff development) affecting successful integration of the Internet in instruction? What are the barriers diffusion (e.g., lack of incentive, instructor's reluctance due either to personal teaching style or to negative attitude towards ICT, limited infrastructure)?

Data collection at the macro level is being carried out every semester on each of the participating courses and their instructors. These instructors are asked to fill out a questionnaire regarding personal information (e.g., gender, position, ICT experience), their needs, and their perception of the contribution of the innovation to the students' learning. A sample of instructors and decision makers are interviewed as well.

Mezzo Level: Shifts in Instruction and Learning

The mezzo level deals with general learning and teaching patterns of students and instructors using Virtual TAU. These patterns are examined in five major domains:

Time/Space Configuration

Information and communication technologies (ICT) challenge the traditional definitions of rigid space and time slots (e.g., access anytime from anywhere). This domain refers to how, and to what extent, the Internet has made academic instruction more flexible in temporal and spatial terms. To answer this question a random sample of about 300 course websites (out of about 1000 courses in the year 2002) is being reviewed and analyzed using a *course website characterization scheme* developed for this purpose.

Information and Content

Content is the major ingredient of any course website (Bonk, 2001). While studying the course, students use various content resources included in the website (e.g., presentations, textbooks, papers, links to other websites, lecturer notes, readings). It is natural that instructors invest considerable effort in planning and developing their course website's contents. Given that a complete overlap between the developers' vision of the course website and the students' usage of it is impossible, it is important to assess the contents consumption patterns (e.g., Sason & Nachmias, 1999). The research objectives in this domain were to assess the extent to which (a) instructors upload contents on their websites, and (b) these contents are consumed by students. Using the data collected in this study, we aim to come up with possible statistical measures of courses' "content consumption". Data was directly collected from computer logs of about 5000 students in 117 courses using Virtual TAU in the academic year 2000/01. Page views for every content unit by every student were recorded and analyzed.

Communication and Interaction

In this domain we are interested in the extent and quality of students' and instructors' communication behavior supported by synchronous and asynchronous communication tools. A typical use of ICT tools in web-based learning is the asynchronous discussion forum. Such a tool provides students with the opportunity to communicate, share ideas and collaborate (e.g., Hara, Bonk & Angeli, 2000). The technical feature that enables storage and accumulation of all participants' contributions allows both students and instructors to review previous interactions and to reflect on different aspects of the learning process within the forum. The major research questions are: To what extent do instructors use forums in their course websites and for what purposes? What are the individual differences among students in forum usage? To answer to these questions, about two hundred courses in the academic year 2000/2001 were screened. Then, we analyzed the messages of all 994 students who studied in 34 courses who used forums extensively, and interviewed students and teachers as well.

Pedagogical and Didactic Solutions

From the pedagogical perspective, innovations are defined in terms of novel didactic solutions reflecting theoretical shifts (e.g., from a behaviorist to a constructivist perception of the learning process). The properties of ICT raise the need to examine fundamental questions regarding the desired features of pedagogical models using web technology (Mioduser, Nachmias, Oren & Ram, 2000), in hybrid face-to-face/virtual courses (Nachmias, Mioduser, Oren & Ram, 2000) or in online discussion groups (Oren, Mioduser & Nachmias, 2002). Research seeks to identify and classify the evolving web-pedagogies ("webagogies") and assess their usage and their effectiveness (e.g., Stephenson, 2001). The primary objective of this study is to identify, collect and classify exemplary pedagogical practices used by selected instructors participating in Virtual TAU (e.g., innovative educational activities, assignments, and didactic solutions). These all are being added to the "webagogies data-base" which will eventually be disseminated throughout the campus. Web-pedagogies are identified and classed through the analysis of the courses' websites, as well as via interviews with their developers and instructors.

Student And Teacher Roles

Increased delegation of responsibility and control over the learning process to the students is one result of the web-based pedagogical innovations. They might promote active and independent learning in which students take responsibility for their own learning, set their own learning goals, create their own learning activities, and/or assess their own progress and/or the progress of other students. ICT might engage students in collaborative, project-based learning in which they work with others on complex, real-world problems or projects. ICT also might provide students with individualized instruction, customized to their different entry levels, interests, or conceptual difficulties (Kozma, 2000). A major research question is whether all this potential is realized in the learning process. Another question is related to students' attitudes toward their use of the Internet for learning and their perceptions of the technology usage. To answer these questions about 3,000 students using Virtual TAU filled out a questionnaire designed for the study. Changes in teachers' role is also a substantial subject for research. Is the shift from "a sage on the stage" to "a guide on the side" a realistic one? Is such shift to be expected from all teachers given their various teaching styles and needs? These and similar questions are currently being answered by a sample of 50 lecturers participating in this study. Data are being collected by means of interviews in two phases: during the first year of usage by the lecturer and two years later.

Micro Level: Features of the Teaching/Learning Process in Specific Courses

At this level we are interested in the actual features and consequences of particular teaching/ learning processes and of explicit behaviors of instructors and students in specific courses. Several studies are being conducted The first study focused on the emergent collaboration activities in six graduate courses using Virtual TAU. Emergent collaboration is the process by which group configuration and transactional patterns evolve among participants in the course of learning. The major research questions were: What are the didactic modes that have been devised for supporting emergent collaboration learning processes, and to what extent do students and teachers participate in these processes? Data were collected by means of log files of students' page-views within Virtual TAU, transcripts of forums and collaborative activities, and unstructured observations. A description, results and conclusions of this study have already been published (Nachmias, Mioduser, Oren, & Ram, 2000).

A second study examined whether social climate evolves in different types of on-line courses.The study compared a hybrid course (involving a mixture of online and face to face interactions) and a distance learning course with reference of the emergence of a social climate This study focuses on the content analysis of messages posted by the students (a detailed description can be found in Oren et al., 2002).

IN ADDITION TEN COMPREHENSIVE COURSE CASE-STUDIES ARE BEING CONDUCTED WITH THE AIM TO PROVIDE MICRO-LEVEL INFORMATION REGARDING THE ACTUAL IMPLEMENTATION OF THE INTERNET IN THEINSTRUCTION (FIVEDURING THE ACADEMIC YEAR 2001/2002, AND FIVE MORE IN 2002/2003). Data collection is done a variety of instruments (e.g., instructor interview ; class observation; student interviews; analysis of the course's website, and learning products).

Preliminary Results

Since most of the studies are still at the data collection stage, we describe only some major results.

At the macro level we observed that the project expanded very rapidly beyond any expectation At the planning phase of the project we intended to implement the web shell in 100 courses over a two-year period, providing each one with a small budget and technical and pedagogical support. Actually, the number of courses in the project increased to 252 in the first year of the project, and in the current academic year (2001/2002) more than 400 instructors and more than 10,000 students from all faculties are using Virtual TAU in almost 1,000 courses. Only 100 courses are receiving financial support from the university. This suggests that the instructors realize the potential benefits of the novel technology for teaching, and are willing to invest their own time and resources in using it. Moreover, many instructors who previously developed course websites using various HTML editors, abandoned these tools and rebuilt their websites using the Virtual TAU shell. This implies that a uniform, easy-to-use, web-supported learning environment is the right tool in the right place for many instructors.

At the mezzo level, several phenomena were revealed. Flexibility in learning time and space was not really achieved so far. Less than 1% of the courses were implemented as complete distance education courses and very few instructors replaced face-to-face classes by web assignments. In the vast majority of the courses the web activities were additions to the ordinary classes . Most instructors view the Internet as content provider rather than a communication facilitator. While all instructors uploaded content to their websites (average of 28 items per website, sd 25), only in 16% of the courses asynchronous forums were included as a teaching mode. Content items include presentations, articles, academic papers, links to websites, simulations, assignments, tests, answer sheets, etc.

From the pedagogical point of view most instructors are using the websites in a basic fashion Only about five percent are developing and using novel pedagogies in which the web has clear added-value (e.g., web-supported collaborative work, replacing face-to-face instruction, web self-test, web peer review). Other instructors (an additional 5-10%) are experimenting and adding new features to their websites in successive runs of their courses (e.g., adding discussion group activities, developing self-tests for students).

As regards to students' usage of the course websites, which in most of the cases were complementary to face-to-face instruction and not obligatory, we found partial and limited usage of the digital medium. For example, out of 5,015 students enrolled in web-supported courses, 1,938 students (38%) did not view *any* content item on the courses' website. Out of 994 students enrolled in courses using asynchronous forums, 478 students (48%) did not participate *even once* in the discussions These figures are considerably large even taking into account that they include students who dropped the courses, and that many technical problems occurred in the first year of the implementation.

Of those students who did use the course website, many did not realize its full potential. For example, 70% of the students accessed less than half of the content items, and less than 5% accessed all content items in a course's website. Figure 1 shows the distribution of the percentage of content items viewed by students in 117 courses. A similar picture was obtained regarding the usage of asynchronous forums, where a few students dominated the discussions.

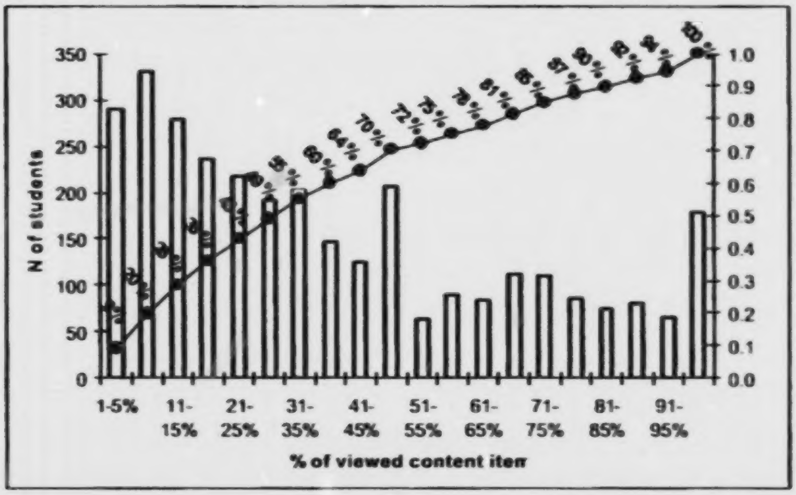

Figure 1: the distribution of the percentage of content items viewed by students(n= 117 courses)

At the micro level specific courses and particular educational transactions were investigated. For example, in one graduate course at the School of Education, critical reading activities were devised as Web-supported and collaborative tasks. Web-support took two main forms: most reading materials were located (as full text and in digital form), or could be reached, in Websites; and Web-shell tools (e.g., forums, mail) supported the students' work. Collaboration was implemented not in the form of pre-structured collaborative tasks, but as working milieu within which learning transactions and dynamic partnerships were expected to evolve in the course of the semester. Figure 2 shows the evolvement of the transactional volume in quantitative terms. The course (22 students) included six forums focusing on critical-reading tasks. For the first two forums, each student entered one message, according to the minimal requirements. By the fourth task participation had increased notably, up to a triplication of the initial values in the last task. The interesting aspect of these figures is that the number of independent contributions remained the same for all tasks, while the difference was made by the increasing amount of responses to other students' messages – from none at the beginning up to 45 in the last task (See Nachmias et al., 2000 for more details).

	1	2	3	4	5	6
▨ Responses	0	0	4	25	16	45

□ Total messages	22	22	27	47	36	67

Figure 2: Number of transactions in six forums of a graduate course using Virtual TAU

A similar observation was made in an undergraduate course in life sciences. This course, created specifically for distance learning, aimed to promote critical reading of scientific articles. The core content of the course comprised six scientific articles which the students were required to read, analyze, discuss and criticize using the asynchronous tools. Both instructor and students reported on an outstanding learning experience involving autonomous learning and collaborative work.

Final Remarks

This paper described the comprehensive research framework for a campus-wide implementation project aimed at integrating the Internet into the academic instruction. The data excerpts presented illustrate the complexity of the project and the many faces of its evaluation. On one hand, we saw enthusiasm and clear evidence of the educational potential of web-supported instruction. On the other hand it is obvious that most instructors and many students still have a long way to go in realizing this same potential. We view this comprehensive research effort as an essential part of the process of change in academic instruction. The research results (primarily at the micro and the mezzo levels) might assist instructors in their continuous efforts to improve their instruction. Updated data and just-in-time insights (primarily at the macro level) can support university leaders and decision makers in managing the technological change in the institution. And finally, research at all levels contributes to the growing body of knowledge about web-supported learning and teaching processes.

Using Technology to Disseminate Classroom Teaching Practices

A. Background

In a recent address at Harvard University's Principals' Club, Richard Elmore pointed out the need to focus on changing teaching *practice*, not *structure*: "[Schools] know how to change…What schools do not know how to do is to improve, to engage in sustained and continuous progress toward a performance goal over time. So the task is to develop practice around the notion of improvement….Real improvement comes when you visit a classroom where somebody is doing the same thing you are - only better." (1)

The idea of improving teaching through enhanced communication among classroom teachers is certainly not new. The difficulty, however, has always been in knowing specifically how to do this, how to provide the time and opportunity for teachers to collaborate on a peer-to-peer basis much in the manner of other professionals. Accordingly, other than reading the occasional periodical, or attending a local conference or workshop, K-12 teachers largely are left to their own devices insofar as classroom teaching practices are concerned.

Today, the Internet has changed this situation. Andrew Lippman of the MIT Media Laboratory recently stated that, because of the Internet, "….we are at the cusp of real change both culturally and societally. This is not just a technology change; the Net is not just a telephone system that talks to computers, nor is it just something that works better than the phone system. We are using communication networks that are fundamentally different from any other communications systems that we have ever had before; they connect groups and social structures….That is what the next five years is all about: Bringing communications to the world." (2)

James Champy, in his recent book on *X-Engineering the Corporation*, makes the same point: "The power of the Internet as a technological development ranks with the advent of electricity, the internal-combustion engine, nuclear power, and the computer itself. It is the ubiquitous network that can link all organizations, and it is driving a fundamental shift in the way organizations operate. Over time, it will not only improve the performance of managers and employees- it will alter the very nature of their work." (3)

B. Current Availability of Best Classroom Practice Examples

Today, the Internet is filled with thousands of Lesson Plans and other descriptive examples of classroom teaching practice. For the most part, these materials are text-based documents and follow no geographic categorization format; that is, most often there is no effort to "regionalize" the Lesson Plans. Undoubtedly, Internet-posted Lesson Plans are excellent examples of particular classroom practices but, nevertheless, the question arises: How frequently are such Lesson Plans adopted by other classroom teachers? In the first place, just the sheer number of Lesson Plans available for review-coupled with the all-too-common lack of time on the part of practically every K-12 teacher, makes it doubtful if many such Internet Lesson Plans are adopted elsewhere. Media-based Lesson Plans are available to a lesser extent but also are seldom adopted since they must be distributed by CD/ROM and other cumbersome delivery methodologies.

C. A New Approach

In 2001, the University of Arkansas at Monticello School of Education obtained a small grant from the NEC Foundation of America to explore the possibility of creating a *National Teacher Education Technology Center*, centered upon the acquisition and web-based distribution of visually-oriented classroom technology practices found effective on a regional basis. The underlying concept behind this effort is that effective classroom technology teaching is already taking place in most K-12 schools; the problem is that, because of the virtually non-existent communications among K-12 teachers, very few people know of such excellent teaching practices. Our idea is that, by more effective use of the Internet, we can improve the communications between technology-using teachers, thereby raising the overall quality of K-12 teaching in the region.

A second key component of this effort is the use of Teacher Education Interns as "change agents." Specifically, we have altered our preservice curriculum so that each Intern is expected to design and to develop at least three technology-based projects each semester of the Internship year. One project will be centered on teaching, one project on student learning, and the final project dealing with some type of tool or utility software. The Intern then summarizes the results of the work in a formal mediated presentation to the faculty, and includes this electronic presentation in his or her Electronic Portfolio.

Since this instructional media production program is already in place, it is an easy step to ask the Intern to identify one or two other teachers at the Internship site that is utilizing classroom technology in some beneficial way and to then record this activity in an electronic format such as Microsoft *PowerPoint®* or other presentation software. This presentation is then vetted by School of Education faculty (Educational Technology Committee) and posted on a dedicated web site for access by other local teachers at that grade level and subject matter area. To date, twelve specific classroom technology applications have been identified, and it is planned to have these materials posted by the end of the current calendar year. We expect to add 20 to 30 additional examples each year thereafter. Also, it is noted that each posted example will include the following information: 1) Purpose, 2) Demonstration, 3) Student Feedback, 4) Resources Required, 5) State/District Standards, and 6) Further Information. Media formats include Text/Still Image, Text/Still Image/Audio, Text/Image/Video, and DVD, although the first examples will be limited to Text/Still Image only. Later, as Internet broadband capability expands, we will include streaming video and other more robust presentation formats.

D. Networking

An important part of this overall effort involves increased collaboration and communication with other area Schools, Colleges, and Departments of Education (SCDEs). Accordingly, and in connection with a U.S. Department of Education *Preparing Tomorrow's Teacher to Use Technology* (PT3), the University of Arkansas at Monticello School of Education hosted an Arkansas Teacher Education Technology Symposium on April 4, 2002 with the intention of forming a Technology Consortium among the eighteen Teacher Education institutions within the State. This proposal obtained good reception and, accordingly, we plan to extend this Classroom Technology Practice sharing idea on a State-wide basis within the next year. Later, as this approach proves successful on a local and regional basis, we can expand the scope of the project nationally through participation in the planned online Project CATALISE Teacher Education Resource Clearinghouse. (4) Again, all of this is possible only because of the ubiquitous availability and inherent communication effectiveness of the World Wide Web; that is, we are now able to do something that simply was not possible in the past.

E. Summary

In a recent article in the *New York Times Magazine*, the Scientific Director of Hewlett-Packard spoke of the "need to design novel mechanisms and institutions so that we can harvest the distributed knowledge that such a gigantic social mind is producing…research consistently finds informed communities making better decisions than any of their members, knowing more, and thinking better than experts. There is this notion of a collective mind, a social mind, and today the Internet allows us to tap that."(5) Elementary, Middle, and Secondary School teachers in every part of the country are making excellent use of classroom technology in their classrooms every day. To improve teaching practice in a most dramatic way, all we need to do to let other teachers learn more of what these other teachers are already doing. It is the purpose of this effort to do just that.

Hybrid e-Learning System
for a Cooperative Linkage between University and Industry

Graduate School of Information Systems, University of Electro-Communications
okamoto@ai.is.uec.ac.jp

Abstract

This paper presents a web-based distance education system that contains synchronous (live) video lectures, asynchronous learning materials with video-on-demand (VOD) archive data, and question & answer functions through digital reporting between a lecturer and students. It is intended to provide a collaborative workplace to encourage interactions among a lecturer/learners. As such, this environment enables learners to exchange their knowledge and their way of thinking, furthermore, to refine/build the knowledge acquired via lectures. One of the main purposes in our research is to build a flexible e-Learning environment by embedding self/collaborative support functions for the digitized live lectures in order to reinforce much more meaningful knowledge and skills. Moreover, we propose an innovative educational method of a cooperative link between a university and an industry for the higher education.

The Industry and University cooperation program is a project of the Japanese Ministry of Education (Mombusho). The target objective of this program is the harmonization of university level educational research, society practice and practical business. The University of Electro-Communications has been appointed by Mombusho to fulfill some specific parts of this program. In this paper we report about our experiences with the introducing of this program, about the framework, settings, actual implementation and first results. We analyze these results and the problems we encountered, as well as offer constructive solutions.

. Introduction

The Industry and University cooperation program is a project of the Japanese Ministry of Education (Mombusho[2]). The objective of this program is not only the completion of an environment where upstanding members of the society with business, industry or university background can learn, but also to the connection and harmonization of university educational research and society practice and practical business. Specifically, the program aims at offering the university student access to the practical, business point of view and practical knowledge on one hand, and the industry and company employee an opportunity to improve oneself and an access to higher knowledge and education[4]. In this way, we are promoting an educational collaboration program that binds university and industry[8].

The goal of the educational program we present is not the building of a large-scale novel curriculum, but the expanding and enrichment of the preexisting curriculum at the graduate school level, by adding company employees' and professional knowledge, and with the specific target of enabling practical, efficient re-training and re-education.

The Japanese Ministry of Education appointed the University of Electro-Communications (UEC) with the enacting of this cooperation program between Industry and University. The target learners are industry students as well as regular students of the university graduate courses, who wish to learn about the new Information Technology (IT) issues. The emphasis lies especially on advanced IT topics. The actual putting into practice involves the extension of the existing curriculum towards more flexibility, in contents as well as in form, in order to allow learning conditions for industry persons as well[5,6]. The implementation method is via long-distance Internet courses, which allow business and industry people to take courses from far sites, without leaving their working places. Moreover, the Internet method allows for flexible hours. Other three universities were appointed to start parallel projects in complementary fields.

In this paper we report about our experiences with the introducing of this program, about the framework, settings, actual implementation and first results. We analyze these results and the problems we encountered, as well as offer constructive solutions.

2. The Program

The subject of career development involving acquiring of high experience and knowledge in the field of information communication technology is an important subject for the future information communication society. The starting courses of the program involve this discipline. The lectures were focused on high information technology, large-scale information system planning and application, and network technology.

For the first year period, the courses involved the following topics:

- Multimedia Communication Technology
- Information Security

Moreover, the appointed lecturers for the industry and university cooperation program are not only researchers and professors from our graduate school, but also company researchers and implementers as well. This is due to the fact that it is important for students to acquire knowledge about not only the theoretical side related to information systems, but also about the practical side.

The lectures are held as collaborative lectures of the type called "*omnibus*" (each lecturer presents only one lecture). Although this new curriculum is of a flexible nature, with many evening hours (to ensure easy participation from far sites) and a relatively concentrated information contents given over a short time period (again, to ensure that company workers loose not too many hours with this program), the UEC graduate school has established a regular credit system for certification purposes. The level of certification is Master level.

3. Experimental situation

Here we report an example situation of a lecture entitled "multimedia communication science/ technology and application". The syllabus of this lecture includes: multimedia and distributed cooperation, CSCL (collaborative system collaborative learning) and collaborative memory, multimedia communication technology, ATM networks, new Internet technology, media representation form and application, data mining, multimedia and distributed cooperation learning support systems, knowledge management, standardization and new business models. The total number of learners attending the lecture was 63, among who only 13 were curriculum students. This time, the distance company sites that cooperated were located near Tokyo, in Kanagawa prefecture. The distance companies were linked via Internet and ISDN circuit, therefore establishing a real time bi-directional information transmitting & receiving environment (details in the next section). Figure 1 displays the geographical distribution of the distance company sites.

From the distance company sites to the University of Electro-Communications, the needed round trip time of the closest site is of 2 hours by public transportation, and for the furthermost the round trip is of about 6 hours. Therefore, considering the hours of time saved and the convenience of the distance education method, the system presents evident merit for both learners from far company sites as well as company managers.

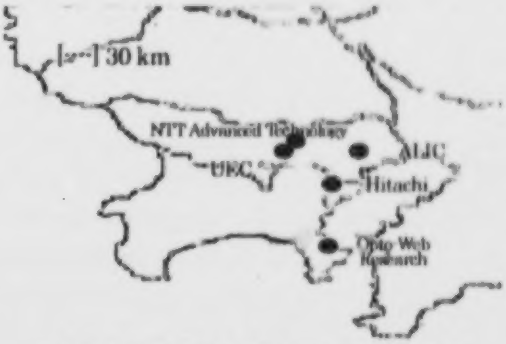

Figure 1. Distribution of distant company sites

4. Distance education system configuration

It is necessary to provide a lecture environment that guarantees the lecture movie, sound and lecture materials presentation distribution for attending students, as well as a dialogue function supporting the communication between lecturer and students. We

BEST COPY AVAILABLE

have implemented these functions by using a VOD (Video On Demand)[3,7] server and a WWW (World Wide Web) server. Figure 2 shows the system configuration of the distance learning system.

Each site has to configure the transmission server and the viewer. Each distance lecture site establishes two dedicated channels: one for receiving only and one for sending only. By connecting respectively the lecture classroom transmission with the distance site reception and the distance site transmission with the lecture classroom reception, bi-directional communication is implemented. Below, each function is outlined.

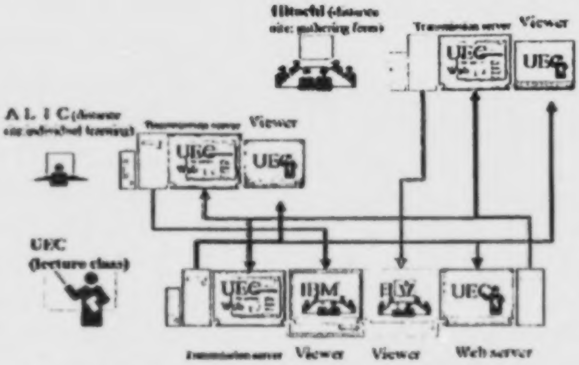

Figure 2. Distance learning system configuration

1) ***Transmission function of lecture's movie and sound*** : the movie and sound of the lecture is distributed to the attending sites with the help of the VOD server real time transmission function[10]. Moreover, in the case of some companies, their Internet access and therefore, the transmission/ reception of lecture movie and sound is not free. To cope with such a network environment, we had to ensure a dedicated Proxy server that relays the distribution of lecture movie and sound between Internet sites, to ensure the data reception. Students at far sites attend lectures by viewing the lecture movie and sound data distributed by the VOD server.

2) ***Lecture material presentation function*** : the lecture materials are formatted as HTML (Hyper Text Markup Language) sources and offered to students via the WWW server. Students use the WWW browser to access the lecture materials and to follow the lecture progress by referring the appropriate page.

3) ***Dialogue (chat) function*** : the communication tool between lecturer and student: Is ensured by a CGI (Common Gateway Interface) program written in Perl (Practical Extraction and Report Language). Lecturer and students access the CGI program via the WWW browser and perform a questions and answers session via the chat terminal screen.

One problem appearing is that the lecture movie and sound data sending and reception conditions depend on the network traffic conditions. Namely, if the reception data has a delay, far site students have difficulty in viewing the lecture, therefore failing to understand the lecture contents. Therefore we have setup a bi-directional communication channel between lecture site and far sites. In this way the communication channel between lecturer and students is guaranteed, independent of the Internet network conditions. Figure 3 shows the distance lecture environment structure (lecture site -> far sites) as well as the interface of both lecturer and students. As can be seen in the Figure, the lecture manager transforms the lecture materials into HTML form and performs the registration into the lecture materials database.

Figure 4 displays the main menu lecture site and attending sites registration window. Concretely, data recorded are machine name (organization name), VOD server IP address and port number and VOD contents stream identifier. Students attend lectures (Figure 4) via our distance lecture environment interface. Firstly, they select the lecture movie "reception" button from the main menu. The system than enquires for the movie to display.

4.1 The Environment for distributed e-Learning Contents

We have developed Web-based learning materials "Multimedia Communication Technology" by HTML, PERL, CGI, Java and VOD materials by Stream Authorware tool. The VOD materials consist of the archive data of movies / sounds from the live lectures in remote areas. According to the stream of movies, PowerPoint manuscript for each lecture is inserted with a synchronous signal in an appropriate position. This environment has three pull-down menus (i.e., a learning objective, a learning mode, and a contents-catalog) to enable learners to select and retrieve whatever they need. This distributing function has been implemented in our original Learning

4.2 The Collaborative Workplace for Question & Answer

We built a collaborative workplace to encourage interactions among a lecturer/learners. In such a case, learners can exchange their knowledge and their way of thinking, furthermore they can refine/build the knowledge acquired via lectures. By a collaborative workplace, we mean a kind of BBS, nevertheless, in addition to Chat function, this workplace enables data/information sharing transmitted from different sites. Figure 5 shows the configuration of relationships between the personal workplace and collaborative one.

4.3 The Assessment Module for Learners

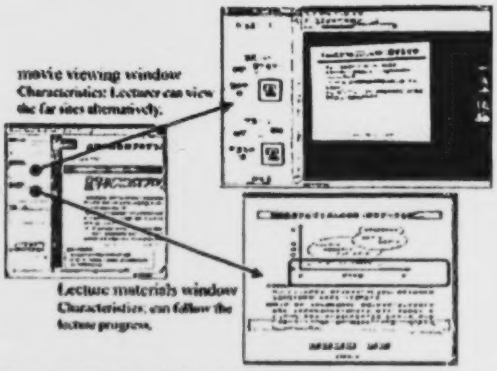
After lecture/web-learning, a test or reporting for learners as a summative evaluation is needed. In this environment, we have provided the repository of a set of test items and reporting tasks according to subjects (course-unit) matched with each learning objective. Students can pick up certain amount of test items or reporting tasks designated by a lecturer, and then reply/send back their answers to *the digital pigeon box*. As such, a lecturer can score and evaluate their achievements online. The simultaneous test is carried out in order to avoid a student's copying behavior from others. Moreover, the *text analyzer* was implemented to check the similarity of the reporting contents from the students automatically. This analyzer was built on the statistical natural language processing method, performing the following functions: picking up important keywords, its occurrence frequency, and co-occurrence of the related word for a certain word.

After pressing the button "lecture site ->lecture movie", the system pops up the "lecture movie playback" window and starts the playback (Figure 6). Moreover, when clicking the main menu's "lecture materials presentation" button, the system presents the lecture materials, too. Students can browse the lecture material via the buttons "advance" and "return". To enable the questions and answers session, the lecturer has to select from the main menu the dialogue tool "startup", action that will generate a "chat" window.

Lecturers attend lectures via a similar procedure to the students. Firstly, they select the lecture movie "reception" button from the main menu (Figure 4). If the students' far sites are equipped with VOD server, video camera, microphone and movie encoder, it is possible for lecturers to receive the image (and sound) of the students attending the lectures. Similarly to the students, the lecturer can

BEST COPY AVAILABLE

view the movie and sound and use the playback function. Moreover, in the case of multiple far sites, the lecturer can switch between them. Questions and answers sessions are possible as full movie and sound exchange, as chat (in text format) or via the regular telephone line.



movie viewing window
Characteristics: Lecturer can view the far sites alternatively.
Lecture materials window
Characteristics: can follow the lecture progress.

5. Evaluation of the Industry and University Education Cooperation Program

The evaluation of the program focuses on how many of the objectives stated in the introduction were actually achieved, and was performed from the 3 points of view enumerated below:

1) *Science and technology aspect:* Here we analyze the operations, functions and the lecture movie and sound data transmission and reception.
2) *Educational aspect:* Here we examine the meaning and significance of the distance education lecture in the frame of the industry and university collaboration project, via questionnaires filled in by the students.
3) *Application and organizational aspect:* Here we collect information from administrators participating in the same program; the focus is on possible improvements of the distance education system, and the data collection is done via work sheets analysis and interviews.

The analysis of the lectures from the above-mentioned points of view is a continuous process. In this section we report the results of points (1) and (2) above.

(1a) Science and technology aspects; evaluation 1: movie and sound data transmission and reception aspect

We have measured the delays, time-lapses and evolution of the lecture movie and sound data transmission. For this purpose, we have analyzed a situation with 3 sites exchanging VOD data. Each site was respectively connected to the Internet via either a high speed -, low speed dedicated circuit (maximum rate 128 kbps), or via a business provider dial up IP link. For the analysis of the transmission, we have collected data from each site on the movie bit rate (Figure 6), movie frame rate (Figure 7) and sound bit rate (Figure 8). As can be seen in the Figures, the maximum real

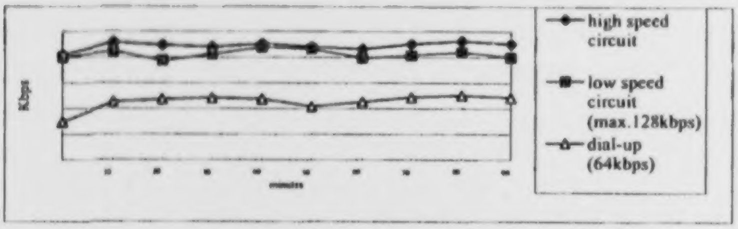

Figure 6. Movie bit rate time series

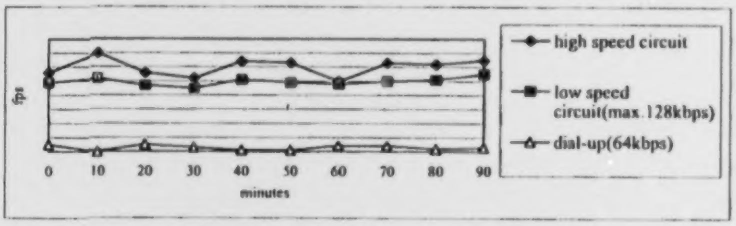

Figure 7. Movie frame rate time series

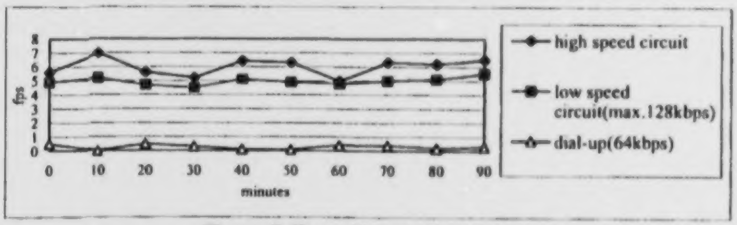

Figure 8. Sound bit rate time series

BEST COPY AVAILABLE

transmission values are, respectively, 48 kbps for the maximum real movie bit rate, 10 fps for the greatest real movie frame rate and 13.2 kbps for the highest real sound bit rate.

We will firstly discuss the movie transmission. For movie bit rates of 40 kbps and above, the lecture transmission is stable, with little interruptions, and the frame transmission is of about 5 frames per second. However, we have experienced that for the dial up connections, reception at the students' far sites is of about 1 frame per 10 to 20 seconds. At this rate, the lecture movie playback window often freezes into a still image for several seconds. Students attending lectures from such sites complained therefore that movie and sound reception is often asynchronous. Compared with the movie data reception, the sound reception was relatively stable for all participating sites. The above experimental result shows clearly that for such distance lectures the limitation is given by the movie reception, and that it is recommended to implement distance lecture environments on network circuits allowing maximum transmission capacity of 128 kbps or above. If a provider IP connection cannot be avoided, the distance lecture environment can be improved with a number of adjustments, as follows.

The first adjustment is related to the lecturer's actions. The VOD system used in our distance lecture environment complies with the H.261 standard, which bases the movie distribution on information compression via a frame prediction mechanism. Namely, the transmitted/ received information weight changes according to the movie data, movie complexity and details, movement intensity, etc. If the lecturer's actions are various, the transmission data weight grows. However, if the lecturer's actions during the lecture are moderate, the movie changes are reduced and therefore the lecture movie distribution can become a little more stable.

As another adjustment, the creation of a dedicated low speed circuit for the VOD server is necessary.

If these adjustments are made, all sites can reach similar bit rate, and the distribution occurs according to the different frame rates. I.e., according to the network bandwidth of the access points, the distribution to high speed circuit students' far sites should be high rate, whereas the low speed circuit far sites should receive low rate movie and sound data.

(1b) Science and technology aspects; evaluation 2: distance education system operatively and functions

We have identified a few possible improvement points concerning lecturing via a distance education system, with focus on application result, operatively and function. Table 1 shows the recommended improvements for the distance lecture environment. Some items in the table point to proposed solutions, others to counter- measures, and again others just present situational examinations.

Table 1: Problems and solutions of the distance learning environment implementation

Encountered problems	Solutions/ Results
Web lecture materials are not synchronous with the lecturer indications. If the lecturer is browsing quickly through the material (as often in the second half of the lecture), the distance learners cannot keep up with the current page.	By using applications with share function, the synchronous display in both lecture room and far sites is possible. One drawback is that the lecturer's personal browsing through the material is not possible anymore.
The circuit speeds of the distance lecture sites differ. Reception is therefore difficult for some sites.	Multiple preparations are necessary for correct movie & sound transmission. The server setup should follow the various requirements of the distance sites.
During the Q&A session, the communication quality is reduced by the existent delay between lecture room and far sites.	There is no fundamental replacement scheme at present. New infrastructure and communication hardware is necessary. Rehearsal prior to the actual Q&A session is useful (or guidance of session by a chair person).
The phone line Q&A sound problems: 1) Noise, hauling; 2) Speaker volume & receiver volume differ.	1) Noise, hauling are caused by the using of a large combination of equipment 2) The volume difference can be cancelled by the circuit resistance value.

(2) Educational aspects evaluation: questionnaire survey

After each industry and university cooperation program lecture we have asked the learners to fill in a questionnaire. The questionnaire contains 21 questions that are a combination of both free description form questions and questions with a 5 steps assessment scale. For the latter, the students should choose the most appropriate of the 5 steps (5: I strongly think so, 4:I incline to think so, 3: Neither Nor, 2: I incline not to think so, 1: I definitely don't think so).

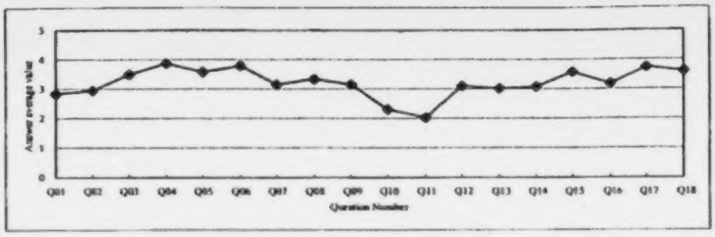

Figure 9. Curriculum questionnaire result average (first lecture in series)

As the industry and university cooperation program lectures cycle is not yet finished, we couldn't aggregate all the questionnaire results yet, and therefore cannot establish conclusive results yet. However, as at present we have finished the first round of lectures, it is possible to derive some suggestions and hints. Figure 9 shows the average answers of the first lecture. Questionnaires were anonymous and 38 questionnaires were returned from the 63 distributed. As the questionnaire (table 2) average is in general around 3-4, the result can be called satisfactory. Especially, questions Q4-6 (about students interest in the subject, the motivating effect of the lecture and about the knowledge they acquired) showed a high score.

Students had an average of 2.8 preliminary knowledge on the subject (Question Q1). This result possibly points to the fact that learners with no prior knowledge, up to learners with some prior specialty knowledge all were interested in the lecture. As the acquisition of high-level specialty knowledge is the main object of the industry and university cooperation program, this is an extremely important pointer. A low result was noticeable especially for questions Q10 and Q11 (regarding the far site transmission situation). Therefore, an important sub-goal and improvement point for the next lectures is the harmonization of the transmission with the far sites. As these were the results of the first lesson in the series, such problems were perhaps unavoidable, and the management and synchronization of lecturer, lecture manager, technical supporters, and teaching assistants was difficult to establish. Some of these problems have already been solved in the following lectures of the same cycle, but as the results were not yet analyzed, we present here our first experiences only, to be of use and serve to guide other educators worldwide.

Table 2: Industry-University Collaboration Program Questionnaire

Q1. Did you have previous knowledge on the contents of this lecture?
Q2. Is there an important connection between today's lecture and your research/ study field?
Q3. Do you think you will be able to use today's lecture contents in your future research/ job?
Q4. Are you interested in the topics presented by today's lecture?
Q5. Do you feel that today's lecture has opened new perspectives?
Q6. Did today's lecture deepen your knowledge?
Q7. Was today's lecture according to your expectations?
Q8. Was today's lecture level appropriate?
Q9. Was today's presented subject of expertise of importance?
Q10. Was the cooperation with the far sites smooth?
Q11. Could you consider the far sites part integrated in the lecture environment?
Q12. Did the lecture materials offered with the lecture help you in understanding the lecture?
Q13. Did lecturing and lecture material presentation run smoothly?
Q14. Was question asking made easy by the offered environment?
Q15. Were today's sound and movie transmission clear?
Q16. Was today's lecture complete and sufficient for you, although designed as a distance education lecture?
Q17. Was the time distribution appropriate for today's lecture?
Q18. Was the time distribution appropriate for far sites, with regard to the Q&A session?

6. Conclusion

In this paper we have presented our experience with the introducing of the industry and university education cooperation project at our graduate school to promote the future high level information communication society based on life-long education. Especially, we have highlighted the following points.

1) The implementation method as well as possible problems of the distance lecture environment offering synchronous study possibility at the lecture site as well as far sites, based on bi-directional communication. In this sense we have concretely presented the lecture form, the representation and presentation technique, as well as the implementation of the questions and answers session.
2) The issue of curriculum integration and certification/ recognition of both on-site and far-site learners. Students in the graduate school as well as far site learners achieve credits according to the Master course credit system. Credits can be obtained course-based or program-based. We have also pointed to the merits of continuous learning and self-improvement for company employees, within our program.
3) Moreover, we have discussed and presented our efforts in the direction of building the infra-structure necessary to support the lecturing within the industry and university education cooperation program. Specifically, we referred to the prior collecting of information, which is to be sent together with the lecture movie and sound transmission. This service packet contains advice and assistance information concerning the lecture contents, the collection and classification of lecture materials, text forwarding, etc.

In this way we hope to support and respond to the forecasted growing future learning demand, especially on advanced IT topics, and to create the chance and environment for a wide area high-level education.

An Evaluation of Scaffolding for Virtual Interactive Tutorials

Claus Pahl
Dublin City University
School of Computer Applications
Dublin 9, Ireland
cpahl@computing.dcu.ie

Abstract: Scaffolding refers to a temporary support framework used during construction. Applied to teaching and learning it describes measures to support a learner to become confident and self-reliant in a subject. In a Web environment scaffolding features need to replace the instructor. We discuss our approach to Web-based scaffolding based on the cognitive apprenticeship and activity theories. We suggest a set of four scaffold types that have made our scaffolding-supported virtual interactive tutorial successful. We present a novel evaluation approach for virtual tutorials that is embedded into an iterative, evolutionary instructional design.

Scaffolding

In increasingly knowledge-based societies, flexible and self-reliant learning becomes more and more important. Internet technologies make learning environments available without restrictions in time and location. However, the reduced direct contact between the instructor and the learner requires additional support. The term scaffolding refers to a temporary support framework that is used in the construction of buildings. Scaffolding is needed in the construction process, but will be removed once the building process is advanced and the building supports itself. Scaffolding has been suggested – the idea can be traced back to (Vygotsky 1978) – as an approach to support learners in their learning effort. The essential objectives are self-reliant learning and the achievement of competency in a domain. Scaffolding is in particular suitable to support active learning approaches. Classically, scaffolding refers to the support learners get from interaction with experts, teachers, and peers, see (Guzdial & Kehoe 1998) or (Suthers 1998). It should enable the learner to accomplish a task in a self-reliant way. The forms of support that can be provided include learning material, feedback, assessment, and demonstration. Three characteristics are essential for scaffolding:

- Modelling: the desired learning behaviour is modelled by providing an adequate learning (infra)structure.
- Support: Targeted support is given to the learner so that the learner can perform a task independently.
- Fading: Over time the support is reduced to let a learner become self-reliant.

The presentation by the instructor needs to be contextualised for the learner. The progress of the learner through the material needs to be coached. Fading of support is an integral part of scaffolding. We can distinguish two dimensions: fading provision of support and fading usage of support. Reflection and, if possible, the articulation of reflection should be encouraged.

Scaffolding is often considered as a part of the cognitive apprenticeship theory, see (Shabo, Guzdial & Stasko 1997) or (McLoughlin, Winnips & Oliver 2000). This theory addresses the problem of coaching a student to perform a specific task. A student learns through active participation in a task in an authentic setting in a close collaboration with a master. The master provides the scaffolding. The process of apprenticeship-oriented learning is characterised by increasing control and ownership by the learner. The cognitive apprenticeship theory puts an emphasis on reflection. A first phase of learning is typically coached, followed by reflection. In the final phase, free and self-reliant learning is supposed to take over. An authentic setting is another key element of a successful apprenticeship model. Its allows a learner to train with or within the subject of concern itself.

In the presence of computer-supported teaching and learning, the notion of scaffolding needs to be adjusted. In particular the World-Wide Web offers new ways for the learner to interact with the environment. The instructor's role in providing the scaffolding support can be taken over by an intelligent software agent. This new context allows innovative forms of support, but there is also the difficulty is to capture the usually verbal communication process between an instructor and a learner in a virtual setting. Elements of the coaching process have to be represented using Web technology. The student progress has to be measured against an expert model. However, the establishment of a successful expert model in the Web context is a problem, since often no topic-specific expertise for learning with the Web exists. The integration of the evaluation of learning and instructional design is therefore imperative. An evolutionary approach to the design of Web courseware in general and scaffolding in particular is needed.

Scaffolding is suitable for active learning. The instructor can be replaced by an intelligent agent that also controls the learner activity. Activity theory is a framework that can help us to redefine scaffolding in the context of the Web. Activity theory is a conceptual framework that can describe the structure, development, and context of computer-supported activities, (Nardi 1997). Its emphasis on the interaction between agents and their environments explains the principle of tool mediation. Tools shape the way humans interact with reality. Tools reflect experiences other people – such as the master in the apprenticeship approach – have made in trying to address similar problems. This experience is accumulated in structural and behavioural properties of the tool. A teaching and learning environment is the tool that provides a student with access to a part of the reality – the course subject – guided by structural and behavioural rules defined by the instructor. Approaches such as problem-based learning, constructivism, or exploratory learning can be derived from constructivist theory, (Dede 1995). Constructivism says that knowledge is constructed by a student, rather than taught to the student. The process of knowledge construction is viewed as deeper than the traditional approach. The student is engaged in solving meaningful problems – we call this active learning. This lends itself to be supported by scaffolding. Interactive educational systems can enable active, apprenticeship-based learning in a constructivist style.

Our objective here is to evaluate the impact of scaffolding on student learning in a virtual interactive tutorial environment that supports the autonomous learner. We will address aspects relating to the acceptance of scaffolding measures, the student behaviour in the presence of scaffolding, and the student performance in an evaluation of our own virtual tutorial. The questions of acceptance and effectiveness of scaffolding shall be answered in this paper. This evaluation is formative in nature. Since learning with Web technologies is not fully understood, an evolutionary approach feeding evaluation results back into the instructional design process is necessary.

A Virtual Tutorial

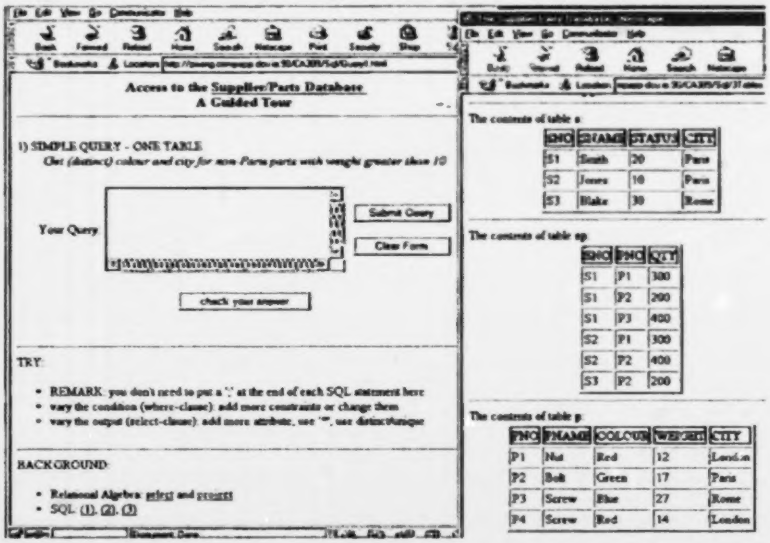
The School of Computer Applications at Dublin City University delivers its undergraduate Database course as a virtual course using Web technologies, (Pahl 2001). A central element is a virtual *tutorial service* that adds a dynamic, interactive dimension to the system, see Fig. 1. The tutorial service facilitates programming in the database language SQL. The service also facilitates learning about the activity of programming. It guides the student through a series of problems with increasing complexity. The central learning focus is on skills, but background knowledge is also required. The learning style can be both structured and unstructured.

The tutorial service offers the student to practice programming skills. A student can type in his/her attempt to formulate a query in the database language SQL and submit the query for execution to remote database server. The server reply will update the current page. In addition to the tutorial, a separate programming interface provides practical material beyond the examples used in the tutorial. This system also allows students to create and query their own databases. The idea behind this service is to support a more unstructured style of learning.

The tutorial is implemented based on a guided tour approach. It starts with a simple example and substantial scaffolding and increases the complexity of the problem and reduces the scaffolding features towards the end of the tutorial. The objective is to implement the apprenticeship model in an authentic setting. The three key aspects of scaffolding are addressed in the design of the tutorial:

- Modelling: The provided structure models the most suitable form of learning and guides the learning process.
- Support: Support in form of context pointers to background material and additional textual advice is provided. This form of coaching is necessary until the students can perform the tasks on their own.
- Fading: The support given through the tutorial is gradually reduced towards the end.

We have used several software-based scaffold types that substitute the interaction with the instructor in our virtual tutorial. Firstly, a guided learning process allows the learner to progress in a structured fashion based on an expert model towards self-reliance. Secondly, assessment and correction features provide necessary feedback and criticism. The system offers individual feedback in form of a check-function. These features are essential to reduce the scope for failure and allow the learner to assess his/her current level of competence. Thirdly, context pointers to background resources contextualise the active elements. Key background resources are audio-visual lecture notes. Finally, comments that resemble advice given by an instructor in a face-to-face coaching process enable the learners to accomplish tasks that they would not be able to achieve on their own. We consider these four scaffolds types as essential in Web environments with little direct contact between instructor and learner. The combination of these types of scaffolds can ensure that the learner is provided with an environment that he/she can interact with in order to accomplish the learning objective. These features provide support for the autonomous learner in the process of becoming self-reliant.



Access to the Supplier/Parts Database
A Guided Tour

1) SIMPLE QUERY - ONE TABLE
Get (distinct) colour and city for non-Paris parts with weight greater than 10

Your Query

TRY:

- REMARK: you don't need to put a ';' at the end of each SQL statement here
- vary the condition (where-clause): add more constraints or change them
- vary the output (select-clause): add more attribute, use '*', use distinct/unique

BACKGROUND:

- Relational Algebra: select and project
- SQL: (1), (2), (3)

The contents of table s:

SNO	SNAME	STATUS	CITY
S1	Smith	20	Paris
S2	Jones	10	Paris
S3	Blake	30	Rome

The contents of table sp:

SNO	PNO	QTY
S1	P1	300
S1	P2	200
S1	P3	400
S2	P1	300
S2	P2	400
S3	P2	200

The contents of table p:

PNO	PNAME	COLOUR	WEIGHT	CITY
P1	Nut	Red	12	London
P2	Bolt	Green	17	Paris
P3	Screw	Blue	27	Rome
P4	Screw	Red	14	London

Figure 1: A Virtual Tutorial

The current implementation of the scaffolds is, however, the result of several years of evolution. Initially based on hypotheses about student learning and student behaviour, feedback from students and interactions with them have substantially influenced the design and implementation of the current scaffolding. Input that has been given to students face-to-face in a traditional delivery of the course is now reflected by features of the tutorial system. In particular the most appropriate learning path has been determined incrementally.

Articulation and reflection are often considered as critical elements in the learning process. Our system is based on two forms of usage. Firstly, a structured approach to learning during term in which students follow the guided tour and work on exercises. Secondly, an unstructured approach where students revise for their exams, re-address aspects that remained unclear before, etc. In-between these two forms of using the system, an implicit reflection phase is present. The students need to assess their current knowledge and skills before starting their exam preparation. A usage evaluation shows a clear distinction between the two forms of usage. In the first usage phase, a clear structure and a prescribed learning process is of advantage for most of the students. Once their skills and knowledge increases, students can determine their own individual needs and most suitable learning processes.

Evaluation Techniques

Acceptance and effectiveness are two key criteria for this formative evaluation of scaffolding. Our data is based on student surveys addressing the student perception, exam results addressing student performance, and Web mining addressing the student learning behaviour. A requirement is that the behaviour evaluation technique captures the essential student activities in relation to the scaffolding types discussed in the previous section. Background resources are linked to the tutorial material, i.e. context is constructed. Links to assessment and correction functions are implemented. The guided tour is implemented as a hypermedia system with suitable navigation support. The navigation behaviour of students within the Web system is the central element of behaviour evaluation.

Web mining is our central evaluation technique. Web mining is the application of data mining to the Web environment. We will use Web mining to evaluate the student behaviour in our virtual tutorial. This will be based on standard Web and data mining techniques (Agrawal & Srikant 1995). However, educational systems differ from commercial systems and students differ from visitors of a commercial Web site (Zaiane & Luo 2001). The student's goal – learning – is a long-termed one. Students usually spent a relatively long time in the system, and they will repeatedly visit the site. Adequate mechanisms need to be in place to support the teacher in developing and evaluating these complex behavioural patterns. The process of learning has to be described and analysed. For this purpose we have developed our own analysis software, which goes beyond standard Web mining technology.

Data mining is defined as the discovery and extraction of information from a database. Web mining is data mining for the Web, i.e. data available in Web-based systems is analysed. The database is here the access log generated by a Web server. Each entry usually contains the user (requester), the date/time of the request and the requested document. In our case of dynamically created pages, the classical problem with Web logs – pages are cached and therefore repeated accesses are not logged – does not apply. The following techniques can contribute to the evaluation of educational systems:

- Session statistics. The Web log is partitioned into sessions for each user. For each session, overall length in terms of time and number of pages visited are available. The average lengths of sessions help us to assess the investment of time for learning activities.
- Session patterns. Session patterns describe the behaviour of students in a session. This includes the sequence of pages that has been visited, whether elements have been repeated, etc. Important is the intertwined use of content and support elements. Their co-occurrence is an indicator of the acceptance of scaffolding.
- Time series of session data. The development of session statistics and also session patterns over time is particularly important. The change of any behaviour in relation to scaffolding features is central since fading use of support indicates the increasing self-reliance of the student. The variance in use over time is central to the determination of the effectiveness of scaffolding.

The increasing self-reliance, which in turn shows the effectiveness of the scaffolding approach, and the success and the learner's competency in the subject measured by exam results and exam/usage correlations have to be shown. A high usage at the beginning shows the acceptance and a considerable usage over time indicates the usability of the scaffolding features.

Evaluation Results

The methods of evaluation address the aspects learning behaviour, student opinion, and student performance. Learning behaviour analysis is based on automatically generated Web server statistics. The Web server statistics are based on data about Web page requests. Database and scaffolding requests for the tutorial have been analysed using this mechanism. Student opinion analysis is based on student questionnaires that survey the student perception. Student performance analysis is based on exam, project and continuous assessment results.

Two observations result from the statistical Web log analysis. Firstly, the data shows that the interactive tutorial is mainly (about 2/3) used during the semester to support students in their coursework and to a lesser extent (about 1/3) for the final exam preparation. Secondly, the programming interface of the tutorial is used in combination with the scaffolding features. This fact is confirmed by the session pattern analysis. This technique shows that a significant number of students use scaffolding features and follow scaffolding links from the tutorial. Web mining can give us a clear picture about the purpose of use. It allows us to identify individual learning sessions and determine the purpose of the sessions. A pattern analysis identifies sequential request patterns and associates them based on structure and content to a purpose.

The survey shows that the students recognise the potential of virtual courses to use different forms of learning at the same time. The interactive tutorial is used in combination with other resources provided by scaffolding. Web mining confirms that in 77% of all tutorial sessions students have also used online course notes at the same time. The students have looked up background material to solve specific problems interactively using the provided navigation support. While nearly all students avail of this feature in their first tutorial sessions, we observed a decrease of scaffold usage during tutorials over time, indicating the increased knowledge and skills of students. The process of becoming self-reliant usually starts with a phase of structured, coached learning, followed by reflection and then more unstructured, self-determined learning. We found strong evidence for this behaviour.

In order to understand how students learn and how they use the support features offered, we need to look at the concrete behaviour. We need to look at how students navigate, whether they repeat units, whether they combine tutorial elements with scaffolds. A pattern analysis can answer these questions.

Tut1; [ExecQuery|Scaffold]; Tut2; [ExecQuery|Scaffold]*; ... ; Tut12; [ExecQuery|Scaffold]**

This is a behavioural pattern describing the intended learning path in our interactive tutorial service. This service consists of twelve tutorial units (*Tut1*, ... , *Tut12*) to be worked on sequentially. Within each unit students can iteratively (*) either execute an SQL query (*ExecQuery*) or use any of the scaffolding features (*Scaffold*). Web mining shows that 84% of all sessions actually follow this pattern of mixing interactive and scaffolding material – most of those that do not are either very short or use a different order.

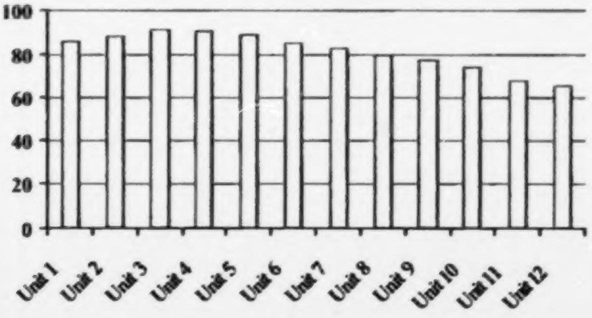


Figure 2: Support of Scaffolding Usage in percent

Fading – the reducing provision and usage of scaffolding features over time – is central in scaffolding. We have analysed time series of Web statistics and behavioural patterns to determine the success in this aspect. Fig. 2 shows the support of scaffolding usage, i.e. the fraction of students that use any scaffolding features in a session, in the twelve tutorial units. It shows that scaffolding features are used extensively by a large part of the student population in all tutorial units. In combination with Fig. 3 – which shows the decreasing length of sessions for the tutorials – and the fact that less scaffolding is provided in later units, it shows that effectively less time and less support is needed for the advanced tutorial units than for the earlier ones. The absolute numbers of scaffold requests have been reduced to around 35% in the later units compared to the first four units.

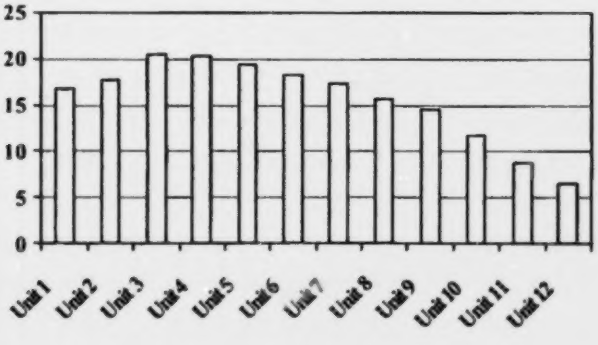

Figure 3: Average Length of Sessions in Number of Requests

BEST COPY AVAILABLE

We have surveyed the student opinion with respect to the usability of the system and the adequacy of the scaffolding approach. The students have pointed out that guidance and in particular the feedback features are central for a successful learning experience, i.e. scaffolding is considered necessary.

Performance is a key indicator for the effectiveness. Over the past couple of years we have constantly improved the scaffolding features of our interactive tutorial. Over the same period we have observed a steady improvement of exam and continuous assessment results.

Discussion and Conclusions

Virtual course technology offers the opportunity of using a course for lifelong learning approaches or distance access to courses. Distance education will play a major role in future education. In order to make an undergraduate course suitable for distance delivery, major functions of a teacher or coach have to be replaced by virtual system functions if direct contact is not possible. Scaffolding is an approach to provide features that can provide the learner with the necessary support. We have implemented a virtual tutorial with scaffolding for the database language SQL – a subject with a reasonable level and complexity of skills and knowledge. The tutorial is anchored in an authentic setting – which has been easy to realise for learning of programming skills. An important feature is that not only knowledge retention is the objective, but also the transfer of knowledge and skills to new application areas.

Our experience suggests that virtual tutorials can substitute the classical instructor-student interaction if sufficient guidance and integration is offered by the system. The interactive services have been accepted by students as a suitable tool in their preparation for continuous assessments, projects and exams. Our main result is that scaffolding can be successfully implemented for a Web-based course if the four scaffold types – guided learning process, assessment and correction, context pointers, advice – are provided. We have shown the success of the approach through the use of a novel evaluation technique – essentially Web mining – to determine the acceptance and the effectiveness of the approach. Guidance of the learning process is the key issue. Contextualised assistance of the learner is necessary to accomplish independence and self-reliance. A key concern is always the cost-effectiveness of a new technology. In our system, the investment into scaffolding features has been reasonable – the key problem was to get it right. This has required an incremental, evolutionary approach to the design and implementation of scaffolding. Our result is different from (Winnips, Collis & Moonen 2000), who have concluded with a more sceptical view on scaffolding. Our context and objective is to make virtual course delivery work. An improvement of classical delivery by Web-based features – as in their case – is not an option for us.

The Web as an open and flexible platform enhances the applicability of scaffolding features. The Web typically encourages students to explore a topic beyond the boundaries of given material. This supports the pro-active and exploratory nature of learning and allows the student to become self-reliant. Ultimately, to make scaffolding most effective, personalised and adaptive systems are the best solution. The needs and behaviour of individual students need to be considered in the provision of scaffolding. A user model needs to be built and student tracking is another prerequisite for adaptive personalised scaffolding. In most approaches to scaffolding, peer-communication and collaboration are central. Computer-supported systems usually offer shared workspaces. We have not considered this aspect since our course is set up to support autonomous learners.

Data Mining Technology for the Evaluation of Web-based Teaching and Learning Systems

Claus Pahl, Dave Donnellan
Dublin City University
School of Computer Applications
Dublin 9, Ireland
[cpahl|ddonnell]@computing.dcu.ie

Abstract: Instructional design for Web-based teaching and learning environments causes problems for two reasons. Firstly, virtual forms of teaching and learning result in little or no direct contact between instructor and learner, making the evaluation of course effectiveness difficult. Secondly, the Web as a relatively new teaching and learning medium still requires more research into learning processes with this technology. We propose data mining – techniques to discover and extract knowledge from a database – as a tool to support the analysis of student learning processes and the evaluation of the effectiveness and usability of Web-based courses. We present and illustrate different data mining techniques for the evaluation of Web-based teaching and learning systems.

Motivation

Web technologies allow us to create Web-based teaching and learning systems that support a variety of different educational features in an integrated form, including audio-based lectures, video-conferencing, interactive tutorials, and various forms of animations and simulations. This opportunity to create novel and innovative course material is currently the focus of an area of active research. Instructional design for Web-based courses is a relatively young discipline. Important quality criteria are the effectiveness of the approach and the usability of the system. Two central difficulties can be identified in this context. Firstly, there is a lack of direct contact between instructor and learner, which makes it more difficult for the instructor to assess and evaluate the quality of teaching and learning. Secondly, new forms of teaching and learning are implemented for which methods of best practice do not exist. Therefore, an evaluation needs to create a broader picture of the process of student learning. Furthermore, an evaluation needs to be incorporated into an incremental, evolutionary instructional design approach.

Data mining technologies can provide essential support for this evaluation of learning processes based on Web technologies (Agrawal & Srikant 1995), (Zaiane & Luo 2001). Data mining is the discovery and extraction of knowledge from a database. Web mining is the application of data mining to the Web. Web logs, created by Web servers that record document requests on the Web, form the database. The classical application domain of data and Web mining are business systems. Some of the classical data and Web mining technologies can be used in the context of Web-based teaching and learning systems. However, teaching and learning systems differ from commerce and business systems substantially. The goal is a different, more long-termed one, which obviously effects the usage of a Web-based system. Frequency, regularity, number and purpose of visits and behaviour are different. As a consequence, some new technologies are needed to address in particular the process of learning. Techniques are required that for example identify and extract the students' learning processes from Web logs.

The objective of this paper is to introduce Web mining as an evaluation technique for educational systems. We will present data mining techniques, including some novel ones, that are suitable for the evaluation of Web-based teaching and learning systems. We will illustrate their use using a virtual course system taught by the first author since several years as a case study, (Pahl 2001a).

Data and Web Mining for Educational Systems

Data mining is concerned with the discovery and extraction of knowledge from a database. Typically, this knowledge can be classified into rules and patterns that help users in analysis and decision making processes. Web mining is the analysis of data in Web-based systems. Usually, the database is the access log created by a Web server. Each request of any text document or other type of resource – a URL – is recorded in the access log. Each entry in this log consists of the requester, the requested URL and time/date of the request. The typical format of an entry is described in Tab. 1.

Field	Description
Client	IP address
Ident	requestor ID (rarely used)
User	(authenticated) user name
Date	date of request
Method	HTTP GET or POST
Request	URL of requested document
Protocol	HTTP version
Status	success indicator (200 is success)
Bytes	bytes requested/transferred

Table 1: Web Log Format

An example of a few requests is the following:

```
136.206.18.130 - rkyne   [08/Nov/2001:11:38:15 +0000] "GET /CA309/ch5ov.html HTTP/1.0"  200 43
136.206.18.14  - lgavin  [08/Nov/2001:11:38:18 +0000] "GET /CA309/ch32c.html HTTP/1.1"  200 2048
136.206.18.16  - bahern [08/Nov/2001:11:38:25 +0000] "GET /CA309/Asgn.html HTTP/1.1"   200 2018
```

Besides HTML-documents, as in this example, any other file type including executables, images and other media can be requested.

Technically, Web mining based on access logs is a server-side evaluation technique that is in contrast to client-side evaluation of Web-based teaching and learning systems. Client-side evaluation can observe the students more directly and evaluates the student behaviour based on data that is acquired at the student's side, e.g. the Web browser. Usually, client-side techniques allow more precise observations. Server-side techniques can not capture all student activities. However, based on suitable implementations, the essential ones can be captured. Most dynamic Web pages result in log entries at the server side, or can generate these, e.g. in technologies like Java applets (Pahl 2001b). An advantage of the server-side technology is the possibility to monitor all students constantly without the need for any additional monitoring equipment to be installed. Data available from the Web logs can provide sufficient and adequate knowledge for the evaluation process.

Web mining for the educational context is based on a central concept, a basic unit of learning: a session. A session reflects a period of active learning of a particular student. The first step in actually applying educational Web mining to Web logs is to clean the logs and to partition the log into individual sessions. We define a session as a sequence $P = <P_1, \ldots , P_n>$ of requests P_i from one student for a period of time in which the student is active. A request P_i is in our case a page request, i.e. a URL. Inactivity for a period of about 20 minutes – a heuristically determined value – indicates the end of a session.

We propose the following techniques as central in a Web mining-based evaluation of teaching and learning systems:

- Session statistics: basic statistics about sessions such as average session length in time or in number of requests.
- Session patterns: the determination of student learning processes extracted from navigation and request behaviour.
- Time series of session data: the analysis of the development of session statistics and session patterns over a period of time.

Besides these three classes, other Web and data mining techniques exist that can provide useful information. Standard tools for Web mining, e.g. (Analog 2002), produce hit lists, i.e. rankings of URLs based on the number of requests for some time interval. This data might be used to analyse the visits of individual pages.

Session Statistics

A session is a sequence of Web log entries that reflects the navigation and request behaviour of a student in a period of active study. Some basic measures can help to answer for example questions about the investment of time per student for a given learning activity. The measurements that can be calculated from the Web log are for example:

- the session length in time,
- the session length in number of requests.

These measurements are simple numerical values derived from the session logs. Simple statistical analyses based on these values that provide some useful information including mean and standard deviations of length measures, or correlations between lengths in time and lengths in number of requests. The purpose of the statistical evaluation is for example to measure the investment of time of a student for the course or for a particular part of it. Any of the results can be compared against the expectations of the educator or instructional designer. Explicitly formulated expectations can form a master model.

There are other statistics that might result in useful insights – as we have briefly discussed in the previous section. The total number of requests by interval or total numbers ranked by resource provide relevant information for an evaluation. These measures give an idea about 'what' resources are used, but not 'how' they are used. The latter shall be addressed in the next section.

Session Patterns

The central knowledge for successful instructional design of Web-based courses is how students actually learn the best in a Web-based environment. Due to the lack of accepted standards of best practice, an evaluation of student learning can lead to useful insights. At the core of this form of evaluation is the extraction of the students' learning processes from the Web logs. Two forms of knowledge discovery are important:

- The extraction of purpose patterns from session data. The purpose pattern analysis is based on classification. The site resources are divided into different parts, e.g. lectures, tutorials, administrative/organisational material, etc. One or several main session purposes can be determined from the resource classification. Then, the overall association of sessions and purposes can be analysed. A somewhat surprising result of a purpose analysis for our virtual database course was that students very often log on to the system to look up organisational resources, such as timetables, exam related material, etc. More than 30% of all session included administrative/organisational elements.
- The extraction of behavioural patterns from session data. The behavioural pattern analysis has the determination of the student learning processes as the objective. The starting point is the Web log. The Web log provides only sequences of resource requests. However, behavioural concepts such as repetition need to be identified. The instructional design might work with concepts such as options and choice. As a consequence, the actual behaviour (as a sequence) has to be measured against an expert model that reflects the instructor's intended or expected learning process and learning path.

The purpose of both analyses is to determine how students learn. This is reflected in the Web logs through the way students navigate and which resources they request, and in which order. As we have explained earlier on, this approach can capture the essential learning activities.

The behavioural pattern analysis is an advanced and novel technology that we will illustrate here. The starting point is the extraction of sequential patterns based on sequences of log entries in sessions. Let $Q = <Q_1, \ldots, Q_m>$ be a sequence of log entries. A sequence $P = <P_1, \ldots, P_n>$ is contained in sequence Q if $P_1 = Q_{i1}, \ldots, P_n = Q_{in}$ such that $i1 < \ldots < in$. This means that each element of the P-sequence can be found in the Q-sequence, and additionally that the P-elements appear in the Q-sequence in the same order in which they appear in the P-sequence. The idea of containment is necessary to filter out activities not relevant for the learning process under investigation – for instance students might go back to previous pages, lookup other pages, even leave the system temporarily. The P-sequence is a candidate sequential pattern. Elements of Q that are not in P are the irrelevant requests. A sequence is called maximal if it is not contained in any other sequence. Maximality allows us to ignore shorter sequences that are contained in others. These would not provide any additional information.

In order to find out what patterns students follow, we need to look at the number of students that follow a particular sequence in a session. A student supports a sequence if the sequence can be found in any of that student's sessions. The support of a sequence is defined as the fraction of all students that support this sequence. A sequential pattern is a maximal sequence that has a certain minimum support. The choice of the minimum depends on the system and the objectives of the analysis. It needs to be determined heuristically. A high minimal support will only reveal patterns that are supported by a vast majority of students. A low minimum will show more patterns, which in extreme cases reflect more the behaviour of individual students than that of the whole group. The site structure, and in particular the degree of choice has an influence on the best choice of the threshold. For systems with a high degree of choice, the threshold should be low in order to detect common behaviour.

The sequential patterns describe the actual behaviour of students. The higher the support for a sequence is, the more often this path is followed by students. Typical sequences with very high support are sequences leading from the home page via a table of contents into some resource page:

HomePage ; TableOfContents ; Chapter1Overview ; ...

The main purpose of the sequential pattern extraction here is that they can be compared to expected behavioural patterns specified by the instructional designer or educator. Sequential pattern determination is a standard data mining technique, see e.g. (Agrawal & Srikant 1995), that we have adapted here to a Web environment. The behavioural pattern analysis, which we are going to present now in more detail, is a novel technique.

Behavioural pattern analysis is a design tool for instructional designers for the development of Web-based virtual courses. A model of the course topology – the navigation infrastructure and the interactive elements integrated into dynamic pages – underlies the specification of behavioural patterns. A behavioural pattern is a path expression on the course topology that describes an ideal learning path. The following is an example from a tutorial part of our virtual database course:

Tut1;[ExecQuery|Scaffold]+;Tut2; [ExecQuery|Scaffold]+; . . . ;Tut12;[ExecQuery|Scaffold]+

This is a behavioural pattern describing the intended learning path in our interactive tutorial service that teaches programming skills in the database language SQL. This service consists of twelve tutorial units *Tut1*, ... , *Tut12*. Within each unit students can iteratively (denoted by +) either execute an SQL query (*ExecQuery*) or use any of the scaffolding features (*Scaffold*) that are provided to support the learner. The semicolon denotes sequential composition, the brackets *[..]* enclose optional elements, and choices are separated by a bar /. The control flow combinators for this path expression language are summarised in Tab. 2.

Name	Notation	Description
iteration	P^+	the page P can be access any number of times, but at least once
option	$[P]$	the page P might or might not be accessed
choice	$P \mid Q$	either P or Q can be accessed
sequence	$P ; Q$	the page Q will be accessed after page P

Table 2: Path Expression Notation for Behavioural Patterns – Combinators

It is important to note that we can see sequential patterns as path expressions of behavioural patterns. We can compare a specification of expected behaviour in terms of path expressions and actual sequential patterns. An ordering relation indicates whether an actual sequential pattern satisfies a behavioural pattern. An ordering $S \leq T$ on path expressions compares actual and intended use and determines whether the actual use conforms with the intended use: $S \leq T$ means that pattern expression S satisfies T. Typically, S will be a sequential pattern and T will be a behavioural pattern. A set of rules – summarised in Tab. 3 – allows us to determine whether a sequential pattern (or a behavioural one) satisfies a given behavioural pattern. In the table, the letters S, T, U, X, and Y stand for path expressions. The expression ST means that S and T are concatenated, i.e. sequentially composed.

Rule	Description
$T^+ \leq T$	means that actual repetitions of T are allowed
$S \leq [S]$	means that the user can choose to access S or not
$SU \leq S[T]U$	means that optional pages T can be left out

Table 3: Pattern Satisfaction Rules

A mathematical property shall be noted: the relation $\leq$ is reflexive, antisymmetric, and transitive, i.e. forms a partial ordering. A weaker variant of $\leq$, denoted with $\subseteq$, can also be introduced: $STU \subseteq XY$ if $S \leq X$ and $U \leq Y$ which allows students to deviate for a while from the pattern path. Deviation, choice and repetition in actual navigation sequences are important concepts to express learning behaviour in a Web-based system.

The final step in the analysis is the determination of the support for a behavioural pattern. The support shall be defined as the fraction of sequential patterns that support the behavioural pattern. A high support for a behavioural pattern that is described by the instructor shows the effectiveness of the instructional design. For the aforementioned tutorial pattern, we have achieved 84% support, which shows that the instructional design has been accepted by the students.

The expressive power of the behavioural pattern notation can even be improved. The notation might be extended to include a parallel composition $P \parallel Q$ which says that pages P and Q can be accessed concurrently – e.g. using two Web browser windows. We shall ignore this possibility here. However, we would like to point out that logging and evaluating multi-window activity is important, and will help to obtain a more accurate analysis of student behaviour.

Time Series of Session Data

Time series are sequences of measurements over a period of time. These measurements can include session statistics and session patterns. The purpose is the detection of change in learning behaviour. This is important for two reasons. Firstly, change might be intended by the instructional designer and the actual occurrence of this change needs to be verified. Secondly, unexpected changes need to be detected.

An example for the first case is an evaluation of scaffolding features that we have carried out for our virtual course (Pahl 2002). Fading use of scaffolds – features that support students in becoming self-reliant and competent in a domain – is an essential characteristic that is expected to happen in an effective scaffolding implementation. An observation that leads to the second case is that, according to our experience, the more students work with computer-supported teaching and learning systems, the more they appreciate this new form of learning. More experience with these systems seems to lead to more effective forms of using the systems, and therefore more effective forms of learning. The evaluation of behavioural patterns can help us to extract the evolution of student learning towards the most effective form of learning from a Web log.

With respect to session statistics, for example the decrease in session lengths for a series of equally difficult tutorial units shows increasing self-reliance and competency of a student. With respect to session patterns we have observed that early patterns often show single purpose use, for example lectures only in a multi-service course system, but later patterns show multi-purpose usage, i.e. integrated usage of different educational services at the same time.

Conclusions

Essential knowledge for an instructional designer confronted with the development of courseware for the Web includes how students learn in a Web environment, i.e. whether students learn effectively and whether the instructional design is effective. In novel environments for teaching and learning, such as the Web, the determination of effective learning behaviour might need to be determined in an incremental and evolutionary way. The integration of instructional design and evaluation into a cyclical development approach is therefore essential. Only an iterative process of design and evaluation allows us determine and evaluate effective learning in a Web environment and to design the most effective courses for the Web. We have presented Web mining technologies for teaching and learning systems that can help us to answer essential questions about student learning in a Web environment. We have presented a set of mining techniques suitable for the educational context – some of them novel techniques developed for the educational context.

The usage evaluation of Web-based systems can be classified into two dimensions: time and space. Usage in time addresses the frequency and regularity of usage, number of accesses, etc. Usage in space is concerned with usage patterns based on the course topology. Our central evaluation techniques for educational systems are evaluations in space. The combination with an evaluation in time can provide additional valuable information. Various tools that provide statistics on numbers of accesses, frequencies, etc. are available – see e.g. (Analog 2002). Tool support is critical for this Web mining-based type of analysis. In our own virtual database course, we usually have between 250000 and 400000 log entries per term. We have implemented our own tool support in particular for the space dimension.

We have looked at using Web mining for the purpose of behavioural analysis. However, the technology can be used to obtain a wider range of information. This could include monitoring individuals or groups of students, or the identification of weak students. The technique presented here is limited to activities in one browser window. If several windows were used concurrently, then this behaviour would have to be recognised as a concurrent one. A corresponding operator for the path expression notation has been suggested. The extension of the analysis towards concurrent activities is planned for the future. In a first step, the notation for behavioural patterns should be extended to encompass parallel activities and corresponding rules to determine satisfaction. In a second step, the pattern analysis should be extended from sequential to parallel patterns.

Abstract: This paper provides a view of learner relationship management that looks to examine the potential for learning systems across an organizational value chain by addressing the potential for learning solutions beyond the Human Resources function in an organization. We identify a return on investment strategy to align the goals of the organization with the goals of the learners. We also look to leverage lessons learned from other technology-based initiatives, namely customer relationship management (CRM) systems and supply chain management systems, both of which also attempt to add value throughout the value chain.

The future rests on how we learn. While this has historically been the lexicon of institutions of higher education, and to some extent the K-12 education system, more and more decisive business leaders are looking toward learning programs and systems as strategic business opportunities. This has caused organizational learning to extend and move beyond the traditional Human Resources departments and squarely into the sights and purview of business unit owners.

To that end, there is a meaningful shift in the view of learning as a way to solve business problems, not just as a means to address training problems. This opens up the door to extend the infusion of instruction, knowledge management, and collaboration to the supply-side and the demand side of the organizational value chain as well as to more effectively and efficiently offer learning solutions intra-organizationally.

Learning in this context has rapidly evolved from traditional stand and deliver training courses and computer- based training environments sponsored, designed, operated, and delivered from the Human Resources department to a wide suite of communication, collaboration, and learning systems that permeate all aspects of the organizational structure. While much of the technological focus of corporate learning initiatives has been placed on Learning Management Systems (LMS), Learning Content Management Systems (LCMS), and reusable learning objects, another, and perhaps more important, advance has also been achieved. Organizations are beginning to see explicit business value from provide exactly the right information, at exactly the right time, in exactly the right format, through exactly the right media to a much larger group of individuals both within and beyond the organizations walls. Along with the additional scope associated with moving learning content and delivery system beyond the walls of the organization, come the additional owners associated with these problems and solutions. More and more we are seeing business unit owners developing and executing learning strategies and projects. Those of use in the learning services field need to realize that these individuals have a set of wants, needs, and desires that we can fill in order to deliver on the promise that we have made on the value of learning within and beyond an organization.

This changing view of organizational learning requires those of us that support such initiatives to look beyond instructional design and content authoring tools and techniques, to a more expansive set of offerings. To maximize the efficiency and effectiveness of any large scale initiative, we must look at a tool box that includes lessons learned from other large scale technological and organizational change initiatives. These include both the technologies to support the initiatives as well as the processes and project management skills required to assure an appropriate payback to the organization. These environments and projects also require us to work together to develop solid business plans and models to leverage all of the costs associated with these initiatives into acceptable return on investment metrics.

Learning from CRM and Supply Chain Initiatives

In the past decade significant hype as well as meaningful advances have been made using technology-based solutions to impact various aspects of an organization's value chain. From the significant growth of customer relationship management (CRM) processes and technologies to provide clients and customers with an more valuable experience with the organization both now and in the future, to the emergence of similar systems to support all aspects of supply chain management, from the acquisition of raw materials, to product creation, and eventually to their ultimate and timely distribution, organizations are looking to introduce both effectiveness and efficiency into all aspects of their operations.

One positive aspect of these initiatives includes the pervasive nature of them across the corporate landscape. Organizations have come to grips with the people, processes, and investment needed to implement large scale CRM and Supply Chain Management solutions. They are beginning to understand the ongoing.investment required to support and maintain these systems that once promised their patrons the vision of a "silver bullet" where business gains would magically appear. The harshest critics of these solutions state that they have been over sold, over hyped, and under delivered.

A key challenge to these environments is often the lack of alignment between the wants, needs, and desires of all relevant audiences that are required to use the system. This misalignment can cause systems to fail, or more typically, to atrophy from lack of consistent use. In either case, the business model and return on investment metrics do not live up to the promise that is associated with these projects at the start of the initiative. As we begin to see why spread interest in more holistic learning solutions within organizations, those of us in the learning services space need to make sure that the alignment of all the stakeholder and user needs are constantly monitored throughout all aspects of an initiative. This includes the project kick off, the design, delivery, and implementation as well as ongoing assessment and evaluation and program refinement.

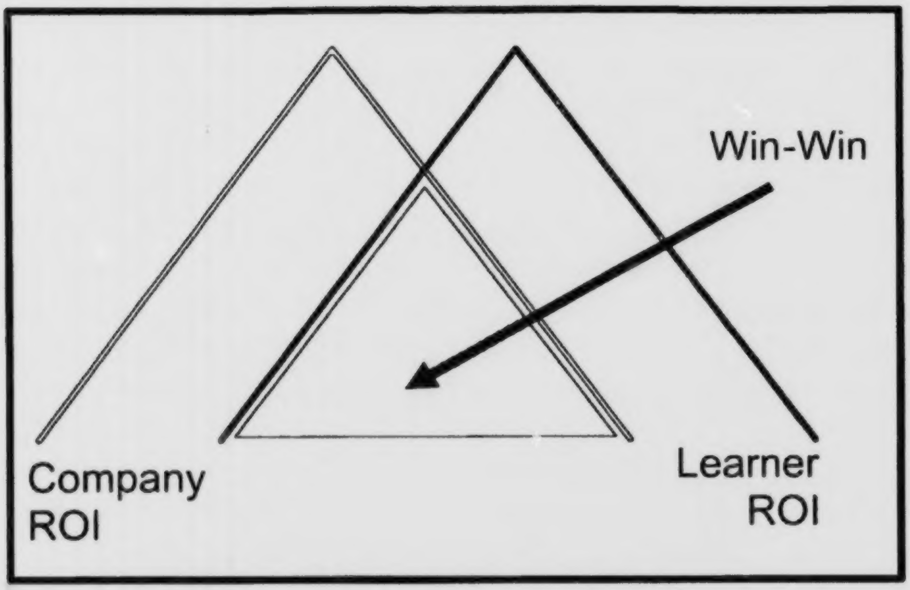

Figure 2. A Multifaceted View of Return of Investment for Learning Systems.

Technological solutions and services organizations

The notion of Learner Relationship Management looks to leverage learning systems, learning processes, and learning content across an organizational value chain. This is critical as organizations move their view of learning from a cost center to a revenue generating (or cost containment) side of their businesses.

Creating business value involves changing behavior, and effectively and efficiently changing behavior requires the design, development, implementation of appropriate learning tools and environments. Our approach to Learner Relationship Management is tailored to aligning the needs of the organization and the wants and needs of the individual at any point in the value chain. Solutions need to deliver timely, specific, relevant information to the learner to effect positive change in their behavior and help them make wise business decisions. We have found that by combining state of the practice learner research with deep industry knowledge we are able to examine and develop personal, meaningful and relevant learning contexts.

The following figure shows an example of how an organization can leverage its content distribution and learning management system to effectively and efficiently deliver learning experiences and assess the success of these systems to a variety of constituencies. Such a model looks to maximize the investment in both the technological infrastructure and the content development process to the largest number of potential audiences. Organizations that are successful in doing so not only increase their reach within their organization landscape but also successfully drop the cost per unit of learning for each audience member.

Such a system requires a systematic and systemic view of learning and a targeted view of the wants, needs, and desires of all potential audience members. This model needs to be addressed in the visioning process for any initiative and then carried through in the projects design, development, implementation, and assessment components of the project. Technologists, instructional designers, content strategists and developers, and user experience design experts need to be have a clear vision of all of the audiences which may user the system and a clear vision of their goals for system interaction. With these criteria clearly defined this team will be able to create an environment that can be successful in meeting the needs of multiple audiences, rather than have to develop disparate system to meet multiple goal states.

Learning Offerings across the Value Chain

To identify the opportunity for learning based solutions across the value chain to be developed for such systems, one must first identify the potential business opportunities and challenges that exist both within and beyond the organization. Again, it is critical to view these challenges in terms of their explicit business needs and to establish success metrics that are based on readily quantifiable business results. The follows are a brief set of examples of how learning solutions can add value across the value chain.

Supply Side Learning Solutions

As organizations look to maximize the efficiency and minimize the churn among their suppliers and partners, learning solutions have the potential to add explicit by providing business process education for suppliers and partners to enhance the effective and efficiency of their workflow. These environments can also provide business process education and establish a community around distributed design and development activities. Likewise they can provide educational experiences around hot topics such as collaborative commerce solutions and plan and execute systems to reduce risk and enhance adoption of these types of solutions.

Intraorganizational Learning Solutions

Internally these types of learning solutions can be an agent for delivery of business process education for employee effectiveness. They can also be the integral system to support internal knowledge management. An organization can also use the learning and content management technologies to design and monitor employee proficiency.

Additional we are seeing an opportunity to create a sense of brand awareness within these systems to help employees feature and differentiation their products and services for enhanced performance. The system can also be pointed to support new employee orientation as well as recruitment experiences to ensure success and reduce turnover.

Demand Side Learning Solutions

As more business unit owners look to implement learning solutions, it is only natural for them to begin to see how they can leverage their learning content and infrastructure to support and enhance their relationship with their customers and clients. Learning solutions hold to potential to support business process education to customize the experience for high volume purchasers. These solutions also cam provide an extended type of marketing channel where an increased customer value can be derived from educationally oriented marketing materials. Organizations can also achieve a first mover advantage by providing their clients exactly the right information to before their job functions, this grabbing additional market share.

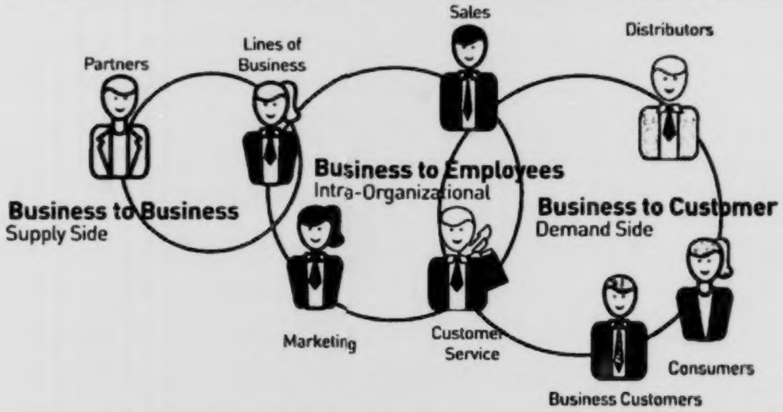

Figure 4: The Business of Learning across the Value Chain

Summary: Return on Investment as the Mantra for Organizational Learning

As stated previously, return on investment has become the current hot topic in the Learning Services industry. People are looking to build out realistic business cases and business models for all of their learning related initiatives. It is important to realize that these models and metrics need to take into consideration both the needs of the learner and the business needs of the organization.

The following is a typical model that looks to place the learning at the center of the learning landscape. Those of us in the learning field have long recognized that placing the learner and the learning context in the center and then developing the pedagogical, content development, community. Technological, and evaluation and assessment models provide the optimal experience for the individual learner.

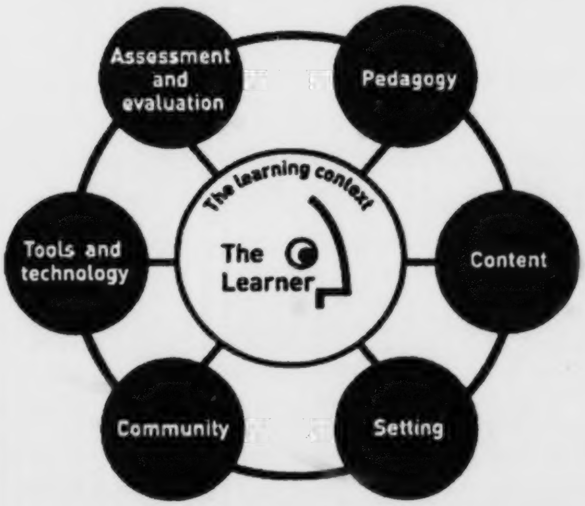

Figure 5: Placing the Learning at the Center of the Learning Universe

What we haven't been so successful in doing is realizing that we need to have similar approach to align the business needs and objectives of the organization in a similar model. By broadening the view of learning beyond their internal organization and structure, companies are able to leverage their investment in both their learning systems and content development costs. They can then rationalize both of these investments against measurable business results.

Combining Cognitive, Affective, Social and Metacognitive Learner Attributes for Assistance in Distributed Learning Environments

Gilbert Paquette, Anne Brisebois and Diane Ruelland

Abstract. Adaptive assistance in distributed learning environments (DLE) provides new and exciting possibilities through the full exploitation of data captured from the interaction of the different actors with information processing, collaboration and self-management tools. We will present a process to build adaptive assistance in a DLE. A distributed learning environment is rich enough to anchor a diversified user model, including the user's competency achievements, his affective reactions to the activities and resources, his collaboration patterns within a group and his metacognitive activity. Together with a model of the group and of the environment, these three models contribute to a diagnosis and a selective display of information intended for human or computerized assistance agents.

Key words. Adaptive Assistance. Student modeling. Distributed learning environments. Intelligent distance learning. Web-based training systems

1. Adaptive Assistance in a DLE

The now ubiquitous availability of multimedia telecommunication opens up a realm of new opportunities for learning in networked environments through a Distributed Learning Environment (DLE). Our DLE model (Paquette, 2001, Paquette,1997) emphasises the concept of process-based learning scenario coupled with information

Individualized tutoring	*Network-based Assistance*
Individualized, learner- computer tutor relationship	Collaboration, multi-actor, multi-agent relationships
Computerized tutor is the main if not the only learning material	Multiple resources integrated into the on-line environment; external information
Assistance from the tutoring module of an ITS	Multiple human and computer assistance agents
Fixed and limited set of instructional strategies	Flexible learning scenarios and strategies
Close guidance to the learner	Learner self management
Specific knowledge, precise goals	More generic, flexible, adaptive goals
Observation data is continuous and closely linked to the target knowledge and skills	Observation data is partial and loosely related to a set of target competencies

Table 1 – Individualized vs network-based assistance or tutoring

BEST COPY AVAILABLE

processing, collaboration, self-management and assistance resources. Basically, the learner proceeds according to a scenario, a network of learning activities, using different kinds of resources to help her achieve the tasks and produce some type of outcome: a problem solution or new information that can be used in other activities. He/she interact with other actors such as trainers, content experts, designers and managers.

Adaptive assistance to these actors, based on knowledge of their activities and productions, is even more important than in the past because of the complexity and flexibility of network-based learning environments. But the problem is quite different than in individualised ITS research (Anderson, Corbett, Koedinger & Pelletier, 1995; Clancey, 1993; Wenger, 1987). It provides large areas of unexplored territories especially towards the full exploitation of the multiple data sources captured from the interaction of the different actors with the resources involved in a distributed learning event. Table 1 provides a brief comparison between individualized tutoring and network-based assistance.

2. Assistance in the Explor@ system

At delivery time, the learner and the other actors interact within a computerised learning environment. Figure 1 presents such an environment where the specialized content of a course is displayed in a browser (the host system) and the generic resources are distributed into five interaction spaces, self-management, information, production, collaboration and assistance, accessible in an Explor@ navigator, according to an actors' role and course specificity. The resources can be generic tools developed specifically for the Explor@ system, generic commercial tools or web resources (used in many courses) such as a technical FAQ, a virtual library, an agenda or a calendar.

2.1 Assistance in a Distributed Learning Environment

Whatever the agents, human or computer-based, the assistance must be « intelligent », that is, informed of the user, of the kind of tasks he is involved in, of the information he has consulted or produced, of the interactions and collaboration with others, and finally of his use of the assistance resources and self-management. In another words, the central question of ITS research, the user model, reappears in distributed learning systems, but in quite a different context [6]. We will give here priority to well informed assistance by human facilitators, without excluding direct intervention from computerized agents.

2. The learning environment model

Using instructional engineering methods and tools (Paquette, 2001, Merril, 1994) a designer can produce the specifications of the host learning environment. The user model will be built in relation to the model of host environment as opposed of the specific implementation of the "physical" system. The advantages of such an approach have been discussed in (Paquette, Pachet, Giroux, Girard, 1996; Paquette, Girard, 1996).

In the Explor@ system, we actually model the host environment into three kinds of hierarchical structures.

- The *instructional structure (IS)* groups the activities or operations that the learner can enact in the environment, from the program or course, down to the modules, the activities and finally the elementary steps where the learner consults, use or produces a resource (document, tool, service, etc.).
- The *knowledge and competency structure (KS)* decomposes a main knowledge object into related parts down to simple skills that apply to knowledge in the structure.

— The *resource structure (RS)* is composed of the list of resource spaces (information, production, collaboration, assistance, self-management) subdivided into individual resources.

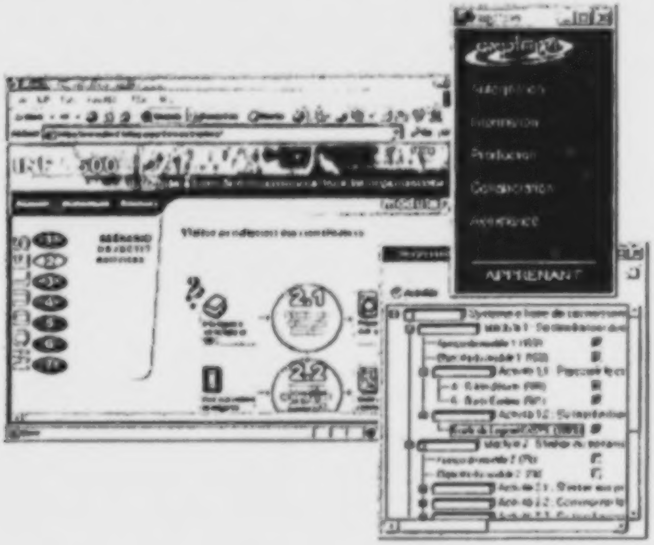

Figure 1 – A host web environment and an Explor@ resource navigator.

2.3 The "progress" part of the user model

To provide adaptive assistance to a learner, we need first to consider his position and progress into each structure of the learning environment model. The definition of adaptive assistance towards progress in the activities is actually done through an interface where the designer of the advisor first describes the IS and the KS, define simple templates to update the user model, and displays an advice or engages in a dialogue with the user (Lundgren-Cayrol, Paquette, Miara, Bergeron, Rivard, & Rosca, 2001). The advisor system also enables the designer to define tailor-made rules for the same purpose.

The learner model is updated essentially in three ways: by the designer's predefined templates or rules, by querying the user or by some action taken by the user can take to modify the model. The progress model is inspectable through a bar graph diagram (figure 1) that changes with the completion of the activities in the IS instructional tree structure.

3. Modeling users and groups

The user model described in section 2 is generic, that is applicable whatever the knowledge domain. But it is incomplete, limited to showing the learner her progress in the activities (in the IS) or in the knowledge and competency acquisition (in the KS). In this section, we will describe a process to build a more complete user model, that fully accounts for the knowledge and competency structure (KS), and also using data from the user's interaction with the collaboration and self-management resources.

3.1 The Modeling Process

Figure 2 – Modeling the learner.

The learner (L), the trainer (T), the designer (D) and the assistance system (S) built by the designer participate to this display of the five sub-processes involved. The first process models the learning environment. It supplies information about the instructional structure, the cognitive structure and the resource structure, targeted towards the type of assistance that the designer intends to build. The second process tracks down the characteristics of the learner through her use of the environment. It embeds cognitive, affective, social and metacognitive attributes. The third process deduces, calculates and compiles group attributes from the individual learner's attributes. All this information is related and analyzed by the fourth process, the diagnostic one, opting to identify learning needs and learner's potential problems. Finally, the compiled attributes, needs and problems are communicated to an appropriate assistance generator, either for the learner, a trainer, a peer helper or a computer agent by the last process.

3.2 User model and the learning environment model

The modeling process draws a dynamic portrait of the user by tracking down a series of data based upon the interactions carried out in the learning environment. This portrait supplies a certain number of cognitive, affective, social and metacognitive attributes obtained by relating the learner's action with resources in the environment.

Cognitive attributes. The cognitive attributes derive from the knowledge and competency structures involved in the learning activities and productions achieved by the learner. We have developed a taxonomy of skills that helps define a scale of competency and performance levels corresponding to the acquisition of a certain knowledge unit (see [7]). The designer defines the entry level (DEC) and the target level (DTC) for each competency to be acquired in a learning activity. Then the learner is invited and encouraged to evaluate and compare, on a regular basis the state of her actual (LAC) and target (LTC) competency level. The trainer assesses the learner's productions or performances, yielding another value for the actual

BEST COPY AVAILABLE

competency (TAC) of a learner. Depending on the relations between these values, it is possible to identify some learner's needs or problems. For example, if TAC < DEC, then the learner does not have the entry level competency stipulated by the designer and a prerequisite course is activated. The distance between TAC and DTC is important especially if a large time interval has elapsed since the beginning of the learner's activities within the course. For each activity in the instructional structure (IS), the associated competencies are evaluated and integrated in the learner's model.

Social attributes. The needed information is obtained by tracing the learner in her use of the collaboration resources in the learning environment, for example emails, forum, chat, videoconference, production showcase and so on. For each of these collaboration tools, some functions will have to be selected and the corresponding data captured. For example, how many messages does a learner send, by email or in a forum, to whom and on what subject? Previous work on forum analysis can contribute to this goal (Ricciardi-Rigault, Henri, 1994).

Affective attributes. The affective attributes are very important in a learner model but hard to track down because of the limited capabilities of today's computers. Emotional states are initialized through the use of an attitude pre-test. A special annotation tool is under construction and will be used to capture changes in attitude and emotions of the learner towards activities in the IS and resources in the RS. This annotation tool can be used anywhere in the learning environment and the learner can use it to enter small written messages, validated through a set of emotional values (Aubé, 2000) ranging from positive emotions (pride, gratefulness, joy, hope), to neutral, or negative emotions (fear, sadness, guilt, anger).

Metacognitive attributes. The Explor@ learning environments put a strong emphasis on self-management tools to help learner plan her activities, evaluate her progress, compare her results with other learners, and decide on a new course of action at a any point in time (Ruelland, 2000). Metacognitive attributes are discovered by the way the learner uses the self-management and assistance tools provided in the learning environment: the frequency of use, the consistency between the planned actions and the progress as well as the kind of modification the learner makes to her training plan.

3.3 Group model and the individual learner models

The model of a group contains group attributes on cognitive, social, affective and metacognitive dimensions. Individual scores of all members of the group participate in the process. In certain cases, the result shows average, median, minimum or maximum scores. In other cases, the distribution of learners in different categories is computed. Still in other cases, it builds the graph of all exchanged messages between learners and analyze it for clusters, number of links at a certain point, transitivity attributes and so on. In the affective evaluation of an activity or a resource, the group model shows how students distribute between emotions.

4. Combining attributes for diagnosis and assistance

We conclude this paper by giving a few examples of the combined use of the three models discussed (environment, user and group) to build a set of diagnostic attributes used to provide adaptive assistance to the learner. We will emphasize the possibility to give advice taking into account, cognitive, social, affective and metacognitive features of the models.

4.1 Diagnostic process

The diagnostic process goes beyond the descriptive models that capture the learner's individual attributes or the group attributes. It participates in the identification of learner's problems and diagnosis. Learning problems uncovered by educational research, particularly in the distributed learning field, feed this process. A diagnosis consists of a problem, its sources of difficulty and the attributes either essential or contributory, describing the problem. During this process, the system watches the manifestations of these attributes in the learner model and establishes, in terms of percentage, the probability that a hypothetical problem is a true problem for a learner.

The problem. For example, persistence has been the subject of numerous researches in the field of distributed and distance learning. The risk of dropout is a problem highly relevant justifying its presence among hypothetical problems.

The attributes. The diagnostic attributes are collected from the attributes available in the three descriptive models of the environment, the learner and the group. They are also obtained through comparisons between these attributes. Table 2 presents a list of examples of such attributes, together with the DLE resources used by the learner, and the model into which they can be found.

Diagnosed attributes	*From resource*	*In model*
1. Distance between the learner actual competency and the entry level defined by the designer	Self diagnosis tool	Learner model, Environment model
2. Values of learner's actual competencies lower than those of the group	Self diagnosis tool	Learner model, Group model
3. Distance between values of learner's actual competencies and those estimated by the trainer.	Self diagnosis tool, Tutor assessment tool	Learner model
4. Delay in the delivery of learner's productions	Progression tool, work plan tool	Learner model
5. Delay in achievement of the activities according to the work plan	Work plan tool	Learner model
6. Slower progress in the activities compared to the group	Work plan tool	Learner model Group model
7. Negative feelings	Annotation tool	Learner model
8. Absence or important decrease of the use of the resources of information, collaboration, assistance and of metacognition.	Progression tool	Learner model
9. High risk of failure (90%)	Inference from the system	Learner model

Table 2 – Example of diagnostic attributes

Some of these data are considered essential while others have a contributory character in that they participate in the description of the problem without being essential to the confirmation of the problem.

The sources of difficulties. The sources of difficulties associated to a problem are going to steer the attention of the trainer or learner on the causes of that problem. They derive from an analysis of the attributes and from their relationship with the cognitive, emotional, social or metacognitive domains. Thus, the sources of difficulty of the learner who demonstrates the attributes 1,2 and 7 of the above list would be of cognitive and emotional nature.

The percentage of credibility. This value is expressed on a continuum for example, persistence / dropout in the above mentioned case and is calculated by a set of rules according to the presence of the essential and contributory attributes in the descriptive three models. The percentage of credibility has two functions. It gives an appreciation of the probability that the hypothesis is really a problem for the learner. It could also be used to establish a priority order among possible problems. This will allow steering the attention of the assistance agent towards some priorities.

All attributes are obtained from the descriptive learner model. The attributes 2, 6 result also from the group model and the attributes 1, 4, 5, from the model of the learning environment. So the three models contribute to supply a critical vision on the learner.

The method described above is an inductive approach to diagnosis (Self, 1990) linking diagnostic attributes to a problem. Other learner problems can be added to the list using an editor to be added to the DLE to allow the trainer to add a diagnosis based on the inspection of the descriptive models. The trainer can either select a problem within a list of hypotheses supplied by the designer or formulate a new problem based on his inspection of the attributes of the descriptive models. He then establishes a concrete relation between the proposed diagnosis and the descriptive model attributes to communicate his perception of the learner problems. This approach informs the designer of learner difficulties not yet listed in the learning environment thus participating to its improvement.

4.2 Communicating diagnostic results

Learners, trainers and designers have different roles and needs regarding the information contained in the models and the diagnostic attributes. It is then advisable to select and organize the information in order to respond to the special needs of each actor.

For example, a learner who wishes to compare his results with those of the group, consults a graphs displaying the group results if the DLE integrates this possibility. In other occasions, a learner has the chance to consult his results and attitudes related to instructional structure before choosing in a range of activities.

The trainer, on his part, receives an orderly list of possible learner's problems. The agent consults and evaluates the appropriateness as well as the type of intervention to establish. The trainer can consult the individual learner's models and the group model before adopting a strategy of assistance. He can also ask to be informed when certain diagnostic attributes have reached a threshold of critical credibility. In the above example, the trainer should be informed about the position of the learner on the persistency/dropout continuum. In accordance with Self's (Self, 1990), all of the attributes need not to be identified. A trainer, who suspects a learner problem, identifies the missing attributes in the learner model and establishes his strategy to obtain the missing information.

The designer as well, has specific needs. This actor will be interested mostly by the group model, the most significant of the three, to improve the learning environment. Inspecting the attributes and problems of the group will direct his attention towards weakness in the design. Learning that a whole group feels anger regarding an activity or experiences difficulty in meeting a target competency will probably help him to implement certain modifications in the cognitive, pedagogical or resource structures.

Conclusion

Proposing summaries tuned to the role of the actor who requested it, approaches the question of learner assistance in a broader way than direct assistance from the system. It is inspired by the "human-in-the loop" approach (Kumar, V., 2001), an approach that was built, right from the start, into the architecture of the Explor@ system and the DLE model we have referred to in this paper. The multi-agent view is focused on a continuous and recursive collaboration between human agents, the actors, and computerized agent, including those giving or helping actors to provide adaptive assistance to the learner.

The approach to adaptive assistance we have proposed here is wide and ambitious. Each dimension of the learner model and the group model has witnessed much research in the past, especially for the cognitive dimension and, more recently, for the social dimension. What we propose here is not to go in depth on any dimension but instead, to use previous research results, to add new elements for the affective and metacogntive models, and to integrate them in combination to detect important learning problems.

Even though we have focused on assistance to the learner, most of what we have described can be adapted to other actors in the environment. Some of our colleagues are presently working on similar schemes to provide assistance to designers.

Finally, we hope to progress in this research in a way to provide guidelines and tools to designers to enable then to integrate new resources in Explor@ DLEs, not only to contribute to learning scenarios, but also to provide ground for adaptive assistance to those scenarios.

Abstract:

The 21st century will require educational changes to meet the demands of industry. Workers in the 21st century must come equipped with a repertoire of both science and technology skills. Currently, many employers are concerned about where they will find highly trained and capable employees for the new century. Therefore, it has become increasingly important to provide female students an opportunity to explore careers in both science and technology. If we are to meet the demands of our technology driven society, all capable students and workers should be given an opportunity to maximize his/her potential. This article reviews the current state of gender equity in science and technology, and provides information on a program that addresses the gender equity issues.

In the Department of Technology and Cognition at the University of North Texas a demonstration project, *Bringing Up Girls in Science* (BUGS), funded by the National Science Foundation is now underway. The goal of this project is to provide: educational experiences in an outdoor learning lab and technology exposure for girls, in grades four and five that will increase girls' interest, participation, self-concept, knowledge, and achievement in the environmental sciences and in technology. The project is the result of an extensive review of the literature on "best practices" for providing effective programs for girls to increase the number of females who choose science and technology careers. The BUGS project is an attempt to bring theory into practice with the help of technology.

Methodology

Thirty-six 4th and 5th grade girls (BUGS participants) currently participate in an after school outdoors science lab at Sam Houston Elementary in the Denton Independent School District in Denton, TX. The contrast group is also participating in two science related over-night field trips; one to a zoo and another to Sea World. Participants for the project were recruited from across the district. As part of the study, BUGS participants are mentored by female high school students enrolled in the Texas Academy for Mathematics and Science (TAMS). TAMS provides an opportunity for talented students in mathematics and science to complete the first two years of college while earning a high school diploma. Each TAMS student will be matched with a BUGS participant. TAMS students will also serve as instructional aides for the outdoor lab. Each TAMS student assists a BUGS participant in developing a science fair project and a hands-on demonstration of a concept learned in the lab that will be presented to parents and future BUGS participants. A two-week summer experience at the University of North Texas' Environmental

Education Center, Elm Fork, will be provided for the academic year participants. TAMS students will serve as educational aides while graduate students in environmental science provide instruction. To increase technology skills for the BUGS participants a project WEB site, chat rooms, computer "pen-pals" and two-way audio-video technology have been established.

The Issues of Gender Equity in Science and Technology

According to Baker and Leary (1995) attracting females to science and technology careers has been, for many years, a well-documented problem. Subrahmanyan and Bozonie (1996) argue that crucial areas of science and technology education, particularly for girls, should occur prior to high school. Programs that address gender equity in science and technology at the high school level are often "too little, too late." Science and technology programs for young female students should address the very specific needs of bright and capable female students. Programs should not strive to be equal to programs for male students, but should be equitable, emphasizing hands-on, real-life laboratory experiences while incorporating verbal/language arts components where many females excel. Cooperative learning and mentoring programs are effective methods for incorporating a verbal/language arts component into such programs. It appears to be most important to encourage science and technology participation at an early age. Subrahmanyan and Bozonie document the need to match curriculum to learning styles. To facilitate gender equity in science and technology it is critical to identify programs that provide learner centered materials at an early age.

On the other hand, differences in the use of computers in our schools seem to be mounting in detriment to some of our student populations. Namely – minority, disadvantaged, inner-city, handicapped, rural and females. Neuman (1991) has suggested that these differences were promoted by inequitable access, distribution and use of computers within and across schools. In schools where limited access is further exacerbated by scheduling patterns favoring higher ability students, reasons for students' limited access were identified as being related to location of hardware within schools, unnecessarily difficult pre-requisites for computer courses, lack of handicapped oriented adaptations on the computer systems and stereotyping oriented software (Neuman, 1991; Rothchild, 2000).

Several other studies strongly suggest that differences in the use of computers in the schools exist more due to gender stereotyping than due to capabilities. Capabilities in the cognitive or affective areas have been found to be consistently the same for both genders (Forsyth, 1986; Elliot, 1993). On the other hand, our society's stereotyping through psychological and social processes may be the main contributor of the gender differences in computer skills and subsequent perceptions (Miura, 1986; Nickell, 1987; Eastman, 1984).

As early as 1986, Holligan (et al) point out that not only is the limited access of computer resources a factor, but goes further to say that these reasons coupled with a 4:1 ration of male to female teachers of computing in the high schools may further deter female students from showing any interest in technology. Boys, on the other hand, are in general favored by software themes, given more mastery opportunities, have more role models to emulate, have less fear of machines and seem to express overall a more positive attitude about the benefits of computers in society than do girls (Miura 1986). Nickell (1987) further concurs with Miura and adds that regular use of computers at school and at home positively affects computer attitudes and that society's stereotypes further encourage such usage only in direct relation to the subject's future sex role functional occupation and what expected computer skills will be necessary.

Rationale for Early Involvement in Science and Technology

Hamrick (1990) conducted a study on Women's Perceptions of Science, which indicated that women harbor stereotypical ideas about science and scientists. Most women believe science is a male dominated field with few opportunities for female participation. Weinburgh (1995) conducted a meta-analysis of the literature on gender differences in students' attitudes toward science. The correlation between students' attitudes towards science and student achievement was explored. Weinburgh concluded that boys display more positive attitudes towards science and that their attitude is highly correlated to their achievement in the subject. Oakes (1990) conducted a study that indicated that the number of students considering careers in the field of science and technology increases very little after ninth grade. Therefore, improving the elementary females' perception of science and technology at an early age would seem to be an essential goal if one is to increase science and technology achievement in female students and subsequently increase the number of females participating in science and technology careers.

Improving Female Involvement in Science and Technology

In a study conducted in 1997, Burkham emphasized the importance of active classroom involvement as a way of promoting gender equity. Methods to increase active involvement include: engage in real life scientific experiments that personify females' interest areas, increase hands-on experience through lab time, allow girls to share research findings through innovative methods that have a strong verbal component (ex. two-way audio visual interaction through the use of the computer), increase opportunities for cooperative learning (Tyler-Wood, 1993).

Technology as a Facilitator

In a recent report, Davis (2000) documented the role that technology can play in an elementary science class designed to increase under-represented female elementary students. Technology can serve as a door-opener or as a gate-keeper for female participation in science. If technology is used appropriately it can serve as a tool to increase an elementary school girl's use of science inquiry and discourse. Possible appropriate use of technology include: conducting science experiments at multiple sites through the use of two-way audio visual technology, the use of chat rooms for scientific discussion, and keeping an on-line journal for science experiments. Davis' research strongly encourages the appropriate use of technology for increasing female participation in science activities at the elementary level.

In 1998, Clements review of the literature finds that computers serve as catalysts for social interaction, with children spending nine times as much time talking with peers while working at computers than while doing puzzles. The review also suggests that the interaction is further influenced by the type of software used and the physical environment surrounding the computer. Beyond Wilson's assertion that the cultural environment has an effect on the content (Stokrocki, 2000), an international study of 303 undergraduate students found that attitude towards computers and computer experience were culture-free constructs. Although the study further confirms that males are more confident about computers than female students, it also found that increased computer experience, number of computer courses completed, and knowledge of computer languages as well as software application packages were enormous contributors to higher confidence levels and overall positive attitudes towards computers (Moon, 1994).

Early on, a similar study conducted, on 247 middle schoolers in the United States, by Eastman & Krendl (1984) had found that the computer task has greater influence on computer achievement than inherent verbal or spatial skills, and that experience using computers reduces sex-related stereotypes. Eastman & Kendl strongly suggest that new technologies foster educational equity.

Conclusions

The literature suggests certain components that should be included in a program designed to increase science and technology career opportunities for females:

1. Hands-on interaction

2. Female teachers as role models
3. Highly capable female mentors for BUGS participants
4. Emphasizing Verbal interaction
5. Working in Groups
6. Using technology to facilitate communication

The BUGS program attempts to move theory into practice by placing proposed promising practices into reality. Currently the program has been under way for a full academic year with all these components in place. Data is being collected on the effects of different components and program practices on the study's population. Analysis of the data will be conducted during the summer. Based on the results, modifications on the procedures and practices of the program will be considered, but the long term impact of BUGS is yet to be determined. Will this theory based program increase the number of females interested in science and technology, and the number of females who obtain high proficiency in skills associated with technology and the environmental sciences? Will BUGS participants enter science and technology careers? Will BUGS participants' achievement scores in science and technology increase?

Student Perceptions of Online Synchronous Courses

Dr. María Victoria Pérez Cereijo

Abstract:

This study identified student reasons for participating in synchronous web based learning environments. Students were interviewed after completing a series of surveys designed to elicit their perceptions of the strengths and weaknesses of the delivery methodology. Responses indicated that both convenience and learning enhancement were considered advantages, while disadvantages included isolation and technology quality.

Background

Our daily routines of having to juggle work, travel, family and for some, the desire to further their education, is being challenged by the increasingly mobile nature of our society (Sherritt & Basou, 1997). In order to accommodate the changing lifestyles of the student population, institutions of higher education are offering courses in many and varied formats beyond the traditional in-class setting. Students every semester are having to make a choice of not only what courses to take to fulfill their degree requirements, but once selected they are having to decide in which campus to attend and/or in which class format. Beyond the usual on-campus class offerings, courses are also being broadcasted either via Vtel/Tangem systems (Distributed Learning) or via the Internet, also known as Web based courses.

Online Class Formats

Web based courses maybe offered either asynchronously or synchronously. For some students, Web based courses are the best solution because of their space independent and sometimes time independent nature as in the case of the asynchronous class format. In the asynchronous setting, professors post all class resources such as handouts (syllabus, schedule and assignments), power point presentations, and even video lectures on a web site. Students can then, using the course schedule and/or other instructional design scheme provided by the instructor, study the materials and complete the requirements to successfully master the objectives.

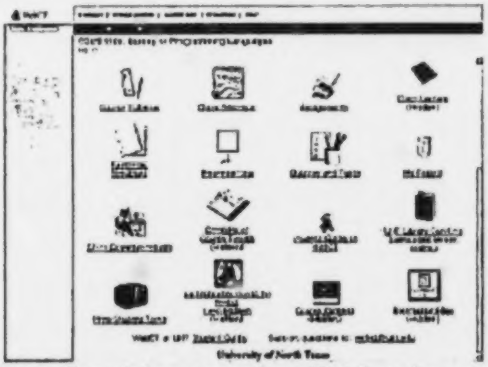

Fig 1 - Sample home page for a Web based course

BEST COPY AVAILABLE

The asynchronous format allows students to "attend" the class at any time from anywhere, thus accommodating not only the students' schedule but also many, sometimes insurmountable, obstacles such as distance from school, lifestyle commitments, and more.

Courses offered in the synchronous format posses all the same characteristics as their asynchronous counterparts except that students must "attend" the live lectures at the pre-arranged class times. Still, this setting offers the space independent feature that allows students to watch the class videos from wherever they choose (home, office, library, other), wherever a computer with an Internet browser and Real Player client software is available.

Fig 2 - Synchronous class format

In this setting students can follow the broadcasted lectures videos with the help of the teacher's power point, and use the chat room to ask questions in real time. So essentially, the difference between the synchronous and asynchronous settings is that students in the asynchronous setting are not able to ask questions in real time. Otherwise, the feel and accessibility to the resources is the same for both settings.

Methodology

A recent study was conducted with a group of graduate students attending an online web-based course taught at the university level. For purposes of this paper only the factors uncovered in the synchronous class-setting portion of the course will be discussed. Students, in this study, were observed, interviewed and asked to complete surveys to determine their perceptions, experience and overall "feelings" for the class format. Questions asked were intended to help find answers to the main research question of "What were the advantages and the disadvantages of the synchronous class format of the course?" A qualitative approach of data gathering and analysis was used to collect students' verbal and textual answers. The three qualitative methods of data gathering used in this study – interviews, observations and surveys – insured the validity of the findings through triangulation (Glaser & Strauss, 1967). As a result, factors were uncovered and grouped as either an advantage or a disadvantage. Further, using the grounded theory approach to data analysis introduced by Strauss and Corbin (1990) relationships between factors under these general groups were established and so related factors were clustered under these emergent categories.

Data Interpretation

Following the grounded theory approach, student statements were carefully read and compared multiple times with other student statements to find commonalities. These commonalities were then identified as the underlying themes, which in turn became the categories. Next, all statements were clustered under the category of "best-fit" following a similar process of analysis. Some students' comments were stored under more than one category because of their broadness. Finally, categories were grouped as advantages and disadvantages. Fig 3 & 4 show the advantages and

BEST COPY AVAILABLE

disadvantages of the synchronous class setting. Although tallies were kept for the number of student responses grouped under each factor, this quantification was not used to determine the true statistical relevance of each factor but to affirm its importance and give future investigators ample evidence by which to judge the appropriateness of the categories. These categories will be considered the variables of future studies.

On examination of the tallies, ***Convenience*** and ***Learning Enhancement*** were the most frequently cited advantages for the synchronous class format (57% of all positive statements). Under ***Convenience***, Economy of Travel, Comfort of Familiar Environment and Similarity of Traditional Environment ranked the highest with a 24% of the total number of statements made. Travel was the one sub-category most often mentioned by students, 53% of the students made a positive statement about the advantages of not having to travel to school. As (Cristina) stated, "I feel I'm making the most of my time. I'm not wasting my time driving when I don't have to." All other subcategories of ***Convenience*** were closely related to these three. Under ***Learning Enhancement***, Technology Factors and Comprehension/Understanding ranked the highest with 19% of all the statements made. Of the two factors, Technology Factors ranked the highest. In this sub-category, students expressed a liking and/or an increased understanding of the technology used, which became a benefit they did not set out to gain. (Leslie) best explained it, "That maybe one reason why I prefer to do something on the Web, rather than just go to class. Because, the challenge in and of itself, just to get on line, and make sure that everything works. That to me, it's really cool!"

The disadvantages of this synchronous online setting ranked highest were related to ***Technology*** and to ***Isolation***. Under Technology (45% of al negative statements), complaints ranged from apprehensions with using the technology, to the video's poor quality, to complaints with the transmission delay over the Internet. As for Isolation (35% of all negative statements), complaints were mostly related to lack of opportunities for informal socialization with the teacher and students. In general, with faster connections and proper technology training, students can be helped to overcome some of the apprehensions online courses present.

Conclusions

In this study, there were 91 negative statements made vs. 230 positive statements made about the synchronous online setting experienced. The figures and the comments appear to support the assumption that online synchronous courses present more advantages than disadvantages. Students found that this classroom setting supports their lifestyle while allowing them to "attend" classes. Students with a hectic life, full of commitments and who live at a distance from school seem to fully embrace Web based courses as an alternative to wasting hours in driving to and from school, and to be able to stay closer in touch with their family and in a more comfortable environment. Online synchronous courses offer students an alternative to coming to campus, and an opportunity to further their studies in an otherwise unlikely situation. Although no one class format has yet been proven ideal for everyone, from some student's perspective Web based courses are making education an accessible reality.

Table 1 – SYNCHRONOUS CLASS FORMAT – *ADVANTAGE FACTORS*

CATEGORY/Subcategory	DEFINITION/responses related to:
CONVENIENCE	Advantages which "save work" in the students' course experience.
Family	the student's increased time to be with other members of his or her family.
Focus	improved concentration and focus on the class material.
Comfort of Familiar Environment	the convenience of viewing the lectures in one's own comfortable surroundings.
Economy	responses related to a savings of resources, including:
Money/Time	
Travel	no driving to and from school-work-home
Eco-System	contributing to saving the environment.
Similarity to Traditional Classroom	responses related to feeling as comfortable with the setting as when being in the classroom or feeling that one is not missing out on any of the interaction or visual cues.
FLEXIBILITY	advantages which allowed students to adjust the course experience to changes in their lifestyles and personal preferences.
Class Backup	having the lectures available in case class had to be missed.
Learning Self-Assessment	assertions made by students that, with this class format, they had acquired the same amount of knowledge that they would have attained in a traditional classroom setting.
Schedule Flexibility	establishing a lecture-viewing schedule around one's work and family schedule.
Viewing Flexibility	the ability to stop or pause viewing the lectures, for any amount of time, due to any type of interruption.
HUMAN INTERACTION	advantages related to the exchange of information among class participants that benefits all involved.
Community Maker	responses related to interacting with others in the classroom for reasons other than course content related, resulting in a sense of camaraderie, a feeling that one knows the classmates.
Communication	responses related to the exchange of information among class participants.
Interaction	being able to have immediate connectivity/interaction with teacher and students.
Socializing	interacting with professor or students for reasons other than course related material.
Immediate Questioning	Ability to ask the professor u other students questions about the class material as soon as need arises.
Body Language Cues	body gestures generated by the speaker that supports oral communication.
Class Discussions	being able to hear or see, oral, or textual communication of other class participants.

BEST COPY AVAILABLE

LEARNING ENHANCEMENT	all those advantages that represent new approaches to a classroom routine and that turned out to be beneficial to the student.
Better Note Taking	for which the video-pause feature was key.
Comprehension/Understanding	the ability to go over the class material more than once for improved understanding depending on need.
Reviewing Lectures	repeatedly viewing the lectures in full increments.
Content Accuracy	repeatedly viewing the lectures in short increments.
Discipline	increased personal **Discipline** – setting and following a viewing schedule.
Multi-Tasking	concurrently performing two or more activities while effectively dividing one's attention.
Technology Factors	while using the technology required to "attend" classes in this format, the student learned to use the new technologies, and, in the process, developed a liking for them.

PSYCHOLOGY	advantages that have, from the student's perspective, beneficially affected the personality or psyche of the participant.
Posing Questions	a) at the student's chosen time but not necessarily during class time, b) once the student had collected his/her thoughts, c) in a more private setting without a face-to-face encounter with the teacher and other students.
Teacher Support	obtaining **Teacher Support** due to a more frequent and structured connection between students and teacher in this setting than when attending classes in a traditional format.
Participation	decreased **Participation** or the choice of not listening to other student's questions, anecdotes, comments and other off-the-track distractions, by fast-forwarding or skipping over portions of the recorded lecture
Self-esteem	An increase in **Self-esteem** or improved self-confidence and self-image by attending class through this format, in a non-threatening environment. (For a student, previous traumatic classroom methodologies had made learning a detrimental experience).

BEST COPY AVAILABLE

Table 2 - SYNCHRONOUS CLASS FORMAT – *DISADVANTAGE FACTORS*

CATEGORY/Subcategory	DEFINITION/responses related to:
ISOLATION	a feeling of being alone and disconnected from the teacher and other students due to a perceived lack of interaction and/or communication.
Absence of Body Language Cues	from the speaker, which eliminated the ability to discern emphasis and other meaning attached to the oral communication.
Absence of Hearing Classroom Discussions	The absence of on-going class discussions and questions on the pre-recorded lectures contributed to students feeling left out and isolated.
Absence of Immediate Questioning	immediate clarification of points made by the teacher was not possible because the lectures were pre-recorded. Although email and phone calls were to be used as the alternate tools for submitting questions to the teacher, not all students felt these were adequate.
Lack of Interaction (no feedback, no socializing)	to communication between student and teacher, and between students, beyond class discussions and immediate questioning. Some students in the course perceived there were a) a lack of socializing opportunities – getting to know other students and the teacher on a personal level – and b) a lack of feedback on the student's progress in the course.
LEARNING ENVIRONMENT	involves all those situations where the student's progress in the course was negatively affected by the environment chosen by the student in which to view the videos.
Interruptions/Distractions	problems in the student's personal environment directly interfering with the smooth, continuous viewing of the lecture.
Lack of Focus	to inability to concentrate on the content of the videos being viewed.
Missed Material	technical problems or student perceptions that contributed to gaps in viewing the lecture.
Lack of Time Flexibility	responses related to having to adjust to the online class schedule in order to view the live broadcast.
Physical Problems	responses related to health related problems that seem to worsen with prolonged use of the computer.
TECHNOLOGY	factor included technology problems that were either perceived as a potential disadvantage or actually experienced as a disadvantage by the students.
Language	loss of **Language** understanding – difficulty understanding lectures over the Internet.
Net Congestion/Buffering	difficulty accessing the videos directly from the department's server over the Internet.
Poor Video Quality	difficulty with the small size, low resolution and jerkiness of the video image.
Other Hardware/Software Problems	difficulty getting comfortable with the technology and the need to make upgrades to permit viewing the lectures.
Typing	responses related to students having little keyboarding skills and experiencing difficulty typing questions in the chat room expediently enough to keep up with the lecture.
Delay	a 20 second delay between actual lecture broadcast and the time the computer would output the image and sound, becoming a nuance when students would ask a question and the teacher had already passed the topic.

AutoTutor Passes the Bystander Turing Test

Abstract: In this study, the Bystander Turing Test (BTT) paradigm is used to determine whether participants rate particular dialog moves in tutoring transcripts to be generated by a computer tutor, AutoTutor, or by a skilled human tutor. Results indicate that participants are unable to differentiate computer-generated moves from those generated by skilled human tutors. Participants did, however, view some dialog move categories to be more pedagogically effective than others regardless of whether the dialog move was generated by AutoTutor or by a skilled human tutor.

Introduction

The study presented in this paper is one of several studies that were recently conducted to determine whether AutoTutor can pass a variation of the Turing test. AutoTutor is a web-based computer tutor architecture that can be used for a variety of content domains (Graesser, Hu, Susarla, Harter, Person, Louwerse, Olde, & the TRG, 2001; Graesser, Person, Harter, & the TRG, 2000; Person, Graesser, Bautista, Mathews, & the TRG, 2001; Person, Graesser, Kreuz, Pomeroy, & the TRG, 2001). AutoTutor's architecture has been described extensively in previous publications, and therefore, will not be addressed here (Graesser, Wiemer-Hastings, Wiemer-Hastings, Harter, Person, & the TRG, 2000; Person, Graesser, & the TRG, 2000; Person, Graesser, Harter, Mathews, & the TRG, 2000; Person et al., 2001; Person, Klettke, Link, Kreuz, & the TRG, 1999; Wiemer-Hastings, Graesser, Harter, & the TRG, 1998; Wiemer-Hastings, Wiemer-Hastings, & Graesser, 1999). The Tutoring Research Group (TRG) has recently developed two versions of AutoTutor, one for computer literacy and one for conceptual physics. The computer literacy AutoTutor is designed to help students learn basic computer literacy topics covered in an introductory course (e.g., hardware, operating systems, and the Internet). The conceptual physics AutoTutor is designed to help students learn Newtonian physics.

Two of the primary design goals of AutoTutor's developers are to create a system that simulates the dialog moves of effective human tutors and to have the system deliver the dialog moves in conversationally appropriate ways. We know that effective teachers and tutors encourage students to take an active role in the learning process by structuring tasks and dialogs in ways that force students to engage in behaviors such as asking questions, recognizing misconceptions, generating explanations, and synthesizing information from multiple sources (Chi, 1996; Chi, Bassok, Lewis, Reimann, & Glaser, 1989; Graesser et al., 2001; Person et al., 2001). Currently AutoTutor initiates a conversation with the learner by posing a question or presenting a problem for the learner to solve. Students learn about computer literacy or physics by engaging in a conversation with an animated agent that remains on the monitor throughout the tutoring session. AutoTutor scaffolds the conversation with a series of dialog moves that are frequently used by effective human tutors (Graesser et al., 2001; Person & Graesser, 1999). The dialog moves included in AutoTutor are Pump, Prompt, Hint, Assertion, Correction, Summary, and three kinds of Short Feedback (positive, negative, and neutral). Although AutoTutor delivers these dialog moves (via the animated agent) in pedagogically and conversationally appropriate ways that enable learners to construct elaborate answers and solutions to questions and problems (Person et al., 2001), it is unclear whether AutoTutor is actually simulating the pedagogical and conversational behaviors of human tutors or whether AutoTutor is producing a set idiosyncratic behaviors that accomplish the same end. The present study is designed to elucidate whether participants view the teaching and conversational behaviors of AutoTutor differently from those of skilled human tutors. The subsequent sections of this paper include the following: (1) an overview of the Bystander Turing Test (BTT), (2) a description of the study being presented in this paper, (3) a summary of the findings and (4) the conclusions drawn from the BBT research.

The Bystander Turing Test

Turing (1950) argued that computers are not capable of thinking and provided several theological, psychological, and sociological arguments in support his position. To determine a computer program's intelligence, Turing proposed several benchmark methods. One such method requires humans to decide whether they are interacting with an actual computer program or another human via computer mediation. According to Turing, a computer could be described as intelligent if it could deceive a human into believing that it was human.

The original Turing test is based on the Imitation Game. In the Imitation Game, the participants are a man, a woman, and an interrogator. The interrogator is physically separated from the man and woman. The object of the game is for the interrogator to determine which participant is male and which is female by evaluating their responses to questions posed by the interrogator. Turing proposed replacing one of the humans (i.e., the man or woman) with a computer. If the interrogator cannot discern whether the responses are generated by the computer or by the human, the computer program is said to pass the Turing Test. Specifically, the computer program is emulating human thought and intelligence if it can process human language, utilize knowledge it has been given before and receives during the interactive session, and use stored knowledge to engage in an intellectual conversation with the learner (Turing, 1950).

The Bystander Turing Test (BTT) is a variation of the original Turing Test (Person, Graesser, & the TRG, 2002). In the BTT, participants rate whether particular dialog moves in tutoring transcripts are generated by AutoTutor or by skilled human tutors. We converged on this variation of the original Turing Test for two reasons that are based on our observations of human tutors attempting to tutor students in computer-mediated environments. First, human tutors have tremendous difficulty responding in conversational real-time to student input. Given that AutoTutor responds immediately to student contributions, noticeable time lags resulting from human tutors' need to think would potentially influence an interrogator's decisions. Second, human tutors frequently make errors when typing their responses. Hence, AutoTutor's text-to-speech generator would mispronounce a considerable number of words, and unquestionably, affect an interrogator's judgments.

Recently Person, Graesser, and the TRG (2002) used the BTT paradigm in a series of studies to determine the following: (1) whether participants could discriminate dialog moves that were generated by skilled human tutors from those generated by AutoTutor, (2) whether the pedagogical effectiveness of the dialog moves generated by AutoTutor differed from the those generated by human tutors, and (3) whether the participants perceived the dialog generated by AutoTutor to be more or less conversationally appropriate than those generated by humans. The results of these studies indicated that the participants could not discriminate whether particular dialog moves were generated by AutoTutor or by human tutors. Further, they reported no mean differences on measures of pedagogical effectiveness and conversational appropriateness for AutoTutor and human-generated dialog moves.

One explanation of why the speaker discrimination (computer or human) was so low involves the dialog move categories. Perhaps the college students used the dialog move category information to diagnostically decide whether a computer or human produced the dialog move. College students may have been penalized in their predictions if they were poor guessers for some categories, but accurate guessers for others. However, previous findings from a dialog move category analysis indicated that the likelihood that the participants believed that AutoTutor generated a dialog move was absolutely equivalent for all of the dialog move categories. That is, the proportion of four, five, and six ratings on the "Who Said It?" question for each dialog move category did not significantly differ (Person, Graesser, & the TRG, 2002).

One interpretation of the findings from the previous BBT studies is that participants were simply not able to discriminate anything (e.g., speaker, examples of effective teaching, conversational appropriateness, or dialog move categories), and therefore, were forced to guess on every rating dimension. The study presented in this paper addresses this very issue by including randomly inserted dialog moves in the conversations. It is predicted that the participants will be sensitive to randomly inserted tutor dialog moves in that they will perceive the random moves to be generated by the computer (i.e., AutoTutor). It is further predicted that the random moves will not be rated as favorably on the Effective Teaching and Conversational Appropriateness assessment questions.

The BTT Study with Random Dialog Moves

Participants. The participants were 64 undergraduates at a small liberal arts college located in Memphis, Tennessee. The students participated in the study to fulfill research requirements for introductory psychology classes.

Materials. The conversations included in this BTT study were constructed in the following way. Two hundred and eighty-two conversations were randomly selected from several thousand conversations that had taken place between college students and the computer literacy AutoTutor. In each of the 282 conversations, a particular AutoTutor dialog move was deleted along with all subsequent conversational turns. Six-skilled human computer literacy tutors were asked to read each conversation and then fill in the blank lines with what they would say to that student at that juncture in the conversation.

After the human tutor responses (i.e., dialog moves) were collected, packets containing 36 different tutoring conversations were assembled. Each packet of 36 contained four types of conversations: (1) conversations in which all tutor dialog moves were generated by AutoTutor in actual tutoring sessions with students (Authentic computer condition, 9 total), (2) conversations in which the last tutor turn was a randomly selected AutoTutor dialog move from another tutoring conversation on the same topic (Random Computer condition, 9 total), (3) conversations in which the last dialog move in the conversation was generated by a human tutor (Authentic Human condition, 9 total), and (4) conversations in which the last tutor turn was a randomly selected human dialog move from another tutoring conversation on the same topic (Random Human condition, 9 total). To the extent possible, the dialog move categories (e.g., Pump, Prompt, Assertion) for both AutoTutor and the humans were evenly distributed across the four conversation types.

Procedure. All participants read and signed an informed consent form before the experiment began. Testing packets were then given to the participants that included 36 conversations. After reading each conversation, participants provided three six-point scale ratings for the last tutor dialog move in each conversation (see Table 1). After providing ratings for all 36 conversations, participants were asked to describe any strategies they had developed for identifying which dialog moves were generated by the computer and which were generated by humans. The analysis of these open-ended responses will not be discussed in this paper.

Table 1. Dialog Move Assessment Questions Used in Study 1 and 2

1. The last tutor response/question is:

1	2	3	4	5	6
Definitely Human	Probably Human	Not sure, but guess Human	Not sure, but guess Human	Probably Computer	Definitely Computer

2. In terms of conversational appropriateness, the last tutor response/question is:

1	2	3	4	5	6
Definitely Inappropriate	Probably Inappropriate	Not sure, but guess Inappropriate	Not sure, but guess Appropriate	Probably Appropriate	Definitely Appropriate

3. In terms of effective teaching, the last tutor turn response/question is:

Definitely Ineffective	Probably Ineffective	Not sure, but guess Ineffective	Not sure, but guess Effective	Probably Effective	Definitely Effective

Results

Three 2 x 2 ANOVAs were performed to determine the effects of Speaker (Computer vs. Human) and Authenticity (Authentic vs. Random) on the participants' ratings of the three six-point scale assessment questions. The means for the three questions are reported in Table 2.

Table 2. Means and Standard Deviations for the Three Assessment Questions

Question	Computer	Human	Total
	Mean (n) SE	Mean (n) SE	Mean (n) SE
1. Who said it?			
Authentic	3.62 (36) 0.12	3.59 (36) 0.13	3.60 (72) 0.09
Random	3.91 (36) 0.12	3.88 (36) 0.12	3.90 (72) 0.09
Total	3.77 (72) 0.09	3.73 (72) 0.09	

2. Conversationally appropriate?			
Authentic	4.24 (36) 0.14	4.41 (36) 0.14	4.33 (72) 0.10
Random	3.45 (36) 0.14	3.25 (36) 0.14	3.35 (72) 0.10
Total	3.85 (72) 0.10	3.83 (72) 0.10	
3. Effective teaching?			
Authentic	4.00 (36) 0.13	4.09 (36) 0.14	4.04 (72) 0.10
Random	3.26 (36) 0.14	3.29 (36) 0.14	3.28 (72) 0.10
Total	3.63 (72) 0.10	3.69 (72) 0.10	

Who said it? (Question 1). The 2 x 2 ANOVA for the "Who said it?" question indicated no mean differences for the Speaker condition, $F(1,140) = 0.07$, $p > .05$. The participants could not distinguish the dialog moves that were generated by AutoTutor (Mean = 3.77) from those that were generated by skilled human tutors (Mean = 3.73). However, the means for the Authenticity condition did significantly differ, $F(1,140) = 5.63$, $p < .05$. Participants considered the Random dialog moves (Mean = 3.90) to be significantly more "computer-like" than the Authentic dialog moves (Mean = 3.60). The interaction between Speaker and Authenticity was not statistically significant, $F(1,140) = 0.00$, $p > .05$.

Conversationally Appropriate? (Question 2). The 2 x 2 ANOVA for the "Conversational Appropriate?" question indicated no mean differences for the Speaker condition, $F(1,140) = 0.02$, $p > .05$. The participants considered the dialog moves generated by AutoTutor (Mean = 3.85) to be as conversationally appropriate as those generated by the human tutors (Mean = 3.83). The means for the Authenticity condition, however, did significantly differ, $F(1,140) = 49.65$, $p < .05$. As predicted, the Authentic dialog moves (Mean = 4.33) were rated as more conversationally appropriate than the Random dialog moves (Mean = 3.35). The interaction between the two conditions was not statistically significant, $F(1,140) = 1.83$, $p > .05$.

Effective Teaching? (Question 3). The 2 x 2 ANOVA for the "Effective Teaching?" question indicated no mean differences for the Speaker condition, $F(1,140) = 0.18$, $p > .05$. The Effective Teaching ratings for the dialogs moves generated by AutoTutor (Mean = 3.63) were equal to those generated by the human tutors (Mean = 3.69). Once again, the means for the Authenticity condition did significantly differ, $F(1,140) = 31.56$, $p < .05$. The Authentic dialog moves (Mean = 4.04) received higher effective teaching ratings than the Random moves (Mean = 3.28). The interaction term for the two conditions was not statistically significant, $F(1,140) = 0.04$, $p > .05$.

Discussion

We can conclude from this study that AutoTutor is achieving many of the design goals of AutoTutor's developers by simulating the dialog moves of effective human tutors and delivering them in conversationally appropriate ways. The findings from this study bolster previously reported BBT results with the addition of the Authenticity conditions. Given that the participants rated random dialog moves less favorably than authentic ones, but could not discriminate the speaker (human or computer), we can be more confident that AutoTutor's dialog move selections are on par with those of human tutors.

The fact that the Conversationally Appropriate means did not differ for speakers and were higher for authentic dialog moves is a promising indicator that AutoTutor is a competent conversational partner. Additional evidence of AutoTutor's communicative competence lies in the fact the conversational ratings for the AutoTutor authentic moves were closer to the more favorable extreme of the six-point scale. Of course, it may be the case that the human tutors adopted the conversational style of AutoTutor rather than generating the dialog moves they would have produced in an actual human-to-human tutoring session. However, even if this was the case, the participants considered the dialog moves of both speakers to be conversationally appropriate. Hence, even if AutoTutor does not emulate the style of human tutors in human-to-human sessions, AutoTutor does deliver dialog moves that are perceived as acceptable and believable.

A Portrait of an E-Learning Teacher as an Art Educator

When I began my journey twenty years ago, my role as an art educator never seemed in question. But with advent of computer technology and the Internet this role needed to be re-addressed.

Today, proponents of education and technology advocate the importance of computer-generated courses in all levels of education. Computers and the Internet have become powerful tools that can enhance teaching and learning in innumerable ways. However, pundits often criticize Web-based Education for ignoring crucial considerations in the development of on-line education, i.e., issues of computer usages, pedagogy/instruction, and curriculum/content. Web-enhanced and online courses have become increasingly popular, but keeping the content interesting and interactivity can be difficult.

The value of the computer and the Internet, like that of any tools, depends upon what purposes they serve and how well they are used. Computer technology and on-line education can be used in positive ways, such as to help make learning more engaging, better address the needs of individual students, provides access to a wealth of information, and encourage students to explore and create—or in negative ways, such as to play mindless games, gain access to inappropriate materials, or isolate students with mundane course material. Many on-line courses in schools, even with up-to-date multimedia computers with high speed Internet access, are not being used in ways that significantly enhance teaching and learning. The reality according to educator Glenn M. Kleiman (2000) is that all this expensive technology will yield little educational return until schools and districts address the need for more professional development i.e., teacher training and in-services, technical support, classroom management, and curriculum integration. [1]

Innovative approaches to addressing these concerns by providing interactivity for online students are key elements in decreasing course attrition rates. The role of the on-line teacher in the success of his/her course, and student attention/retention and achievement is clearly based on combining available technology and resources to add interest and interactivity to online courses. Only by developing innovative curricula can these courses succeed.

One strategy might be by building a course by interconnecting Curriculum Web Design and Instructional Development within the context of delivering a "good story." As educators we need to approach on-line education as modern day storytellers or troubadours, using the computer as our flute, drawing our student

---

audience to the screen and keeping them engaged with a well-told and developed story. Storytelling had its origin in play activities, with gifted but ordinary folk entertaining their particular social group informally. Gradually these activities were included in religious rituals, historical recitations and educational functions. Ellin Greene defined storytelling as:

"...an art...taking the printed words in a book and giving them life. (World Book Encyclopaedia, 1976)"

In web-based learning, this role is even more critical, as an on-line instructor one has to overcome potential barriers caused by technology, time, and place in the hopes of creating an optimal environment for achieving educational goals.

Over the past two years, as an asynchronous online learning instructor and an artist, I have created and developed on-line learning at the high school and elementary levels of education for the Toronto Catholic District School Board. The following reflections come from educational research, as well as personal experience as an online learning student, instructor, and instructional designer.

The purpose of this paper is to examine the process, implications, and ethos of becoming an e-learning teacher with an art background. What is the role of a teacher in developing and teaching this new pedagogy? Does it matter what background you bring to e-teaching? Is the role of the on-line teacher; a critic, a guide, an initiator, a transmitter, a facilitator, or is the role of an on-line teacher like a scientist? What makes great web-based learning? Finally, this paper presents the researcher's broad definition of e-learning, and reflects on his present stage as an e-learning teacher.

Reliable Assessment With CyberTutor, A Web-Based Homework Tutor

David E. Pritchard and Elsa-Sofia Morote
Research Laboratory of Electronics
Massachusetts Institute of Technology
United States
dpritch@mit.edu , smorote@mit.edu

Abstract: Socratic electronic homework tutor, CyberTutor can integrate effectively instruction and assessment. CyberTutor assessment has about 62 times less variance due to random test error than a three-hour final examination, and 53 times less variance than twelve weekly tests. This improvement results from the combination of three factors. First, the typical student interacts with CyberTutor 16 times longer than the 3-hour final exam and 10 times more than 12 weekly tests together, diminishing the effect of lucky guesses and careless errors. Secondly, by considering requests for hints, solutions, and importantly the number of wrong answers and the time the student takes to complete each part of the problem, CyberTutor can make a better determination of the student's skill on a problem. Lastly if a problem is too difficult for the student as presented, CyberTutor's hints and responses to wrong answers systematically adapt the difficulty of the problem to the student's skill level.

Introduction

It is the end of semester and you have two students waiting to talk with you about their score in the final exam. You know what they want. Are you sure they deserve to fail? Are you wondering if that student who miraculously passed, deserved to pass? You are a fair teacher, and put all your effort into constructing a fair final exam but have you ever tested how reliable your final exam was? Do you really believe that a 3-hour final exam will accurately reflect the precise "skill" level of every student?

This paper demonstrates that an electronic tutoring program can collects data that enables a far more reliable assessment of students' skills than a standard examination. The following scenario illustrates the basic idea: Imagine that a rich ship-owner has hired Socrates to tutor his children. At the end of the month he desires to assess the amount they have learned. Would you advise him to:

a) Administer a standardized hour-long test to the children? or
b) Ask Socrates how much they have learned?

The answer is straightforward. Clearly Socrates' many hours of individual interaction enables him to form a far more accurate and nuanced assessment of each student than could be provided by a one-hour test. Moreover, this integrated assessment is continuously updated and is used by Socrates to adjust the pace and content of the session. Importantly, this continuous integrated assessment is available without the stress and time loss of traditional testing.

Tutoring with Assessment

The recent advances on the Internet and World Wide Web have brought attention to the world of Web-based education. There is an increasing demand for use of computerized educational aids by students and faculty (Cao & Bengu, 2000). Teachers are not only using electronic homework systems but recently there has been growing interest in using tutoring agents in education systems (Boy, 1995). The educational impact of real-time processing and reporting results of diagnostic electronic homework of results is recognized by Just in Time Teaching (Novak et al., 1999). It enables classroom instruction to be efficiently tuned to students' needs. The essential element is feedback between the web-based tutoring and classroom activities. The positive effects on learning of these web-based electronic homework tutors have been confirmed by several studies such as Mestre et

BEST COPY AVAILABLE

al. (2000); Ogilvie (2000); Thoennessen & Harrison (1996) and Pritchard & Morote (2002a). Some of these electronic systems also eliminate the task of grading; enabling teachers to shift efforts to instruction, but only few offer an integrated system of tutoring and assessment.

Researches at Massachusetts Institute of Technology have built "CyberTutor" a Socratic electronic homework tutor. CyberTutor has a fine-grained assessment algorithm which permits the identification of skill deficiencies in foundational skills as each student moved through the course. This would allow tutors (or perhaps additional CyberTutor problems) to remedy the deficiency before it causes irreparable harm to the student. Additionally, knowing the class' skill profile on each detailed topic could allow the teacher's next lecture to review topics that were not being well learned.

The CyberTutor analog of Socrates' assessment is a skill profile – that student's skill rating on each of a set of predetermined topics. A topic could be an item in the regular syllabus like momentum, but it could also be a foundational skill like vector components, a general skill like using dimensions and units, or a conceptual topic like Newton's concept of force.

Because it is continuously updated, skill profiling has the following potentially revolutionary benefits for the student and the teacher

1) It is vastly fairer to use as the basis of a grade because of its dramatically smaller random error
2) Students who have gaps in their foundational skills can be identified and helped early in the course
3) The skill level of the class on the current topics can guide the teacher's allotment of class time – a new form of Just in Time Teaching.
4) The assessment is sufficiently detailed to be used to predict the student's grade on a standard test, for example a midterm or the AP physics test.
5) Teachers can therefore dispense with some examinations and increase class time

Skill profiling can have a revolutionary impact if it is used as a grade (e.g. your grade on the momentum homework is your skill at momentum on Thursday night at 10PM). This could replace the students' current strategy of "avoid lost points" with the much improved one "learn the most."

Methodology

Using data of Introductory Newtonian Mechanics, course 8.01 teaching at spring 2001 at MIT we evaluated reliabilities of the final exam, weekly tests, and CyberTutor. Over 90% of the students taking 8.01 in the spring term have previously attempted this course without being able to learn the problem solving skills demanded by the 8.01 final examination. Besides course elements such as class participation, written homework, group problem solving, and a Socratic electronic homework tutor, the students were given 12 weekly tests during the semester and a final exam.

We note in passing that this particular final exam had three features that should give it less error than typical physics finals. A standard test (Mechanics Baseline test) was used for 1/3 of the Final. The remainder was divided into basic skill problems and complex problems which accentuate the performance of different students. The total test requested 47 specific responses from the students. In comparison, the 8.01 final in the preceding semester required only 28, and therefore probably had larger relative statistical fluctuations.

Testing Reliability

By definition, someone taking a test or other assessment measure achieves the "observed score." The observed score is thought to be composed of two different components: The true score, an exact measure of the amount of the trait or skill assessed, offset by a random error score (Observed score = True score + Error score). The error may result from individual student responses to particular questions (Manson & Bramle, 1997) or external conditions such as fatigue and noise.

The variance of the observed score is composed of the variance of true scores and the variance of error. Then, $\sigma^2_o = \sigma^2_t + \sigma^2_e$, where, σ^2_o = variance in observed scores, σ^2_t = variance in true scores, and σ^2_e= variance of error

The "reliability" of a test or assessment measures its repeatability or freedom from random testing errors. An assessment is considered reliable if it would give us the same result over and over again. By definition, the reliability is the ratio of variance of the true skill divided by the total variance of the measurement (observed variance), σ^2_t / σ^2_o. The reliability provides a direct guide to the reproducibility of the grade between two similarly prepared tests (odd or even numbered questions) on equivalent material. If reliability = 1, there is no error in the test.

A standard method of determining the reliability of an assessment is to divide the test questions into two subtests, for example the odd and even questions if they were equal in coverage of topics and difficulty. If the resulting subtests determine skill with perfect reliability, each student would receive the same score on both subtests, and a scatter plot of each student's scores on the "odd (a)" and "even (b)" subtests would lie on the diagonal. We compute the reliability of the various assessments considered here from the *uneven split reliability formula* (see Pritchard & Morote, 2002a for derivation). This method does not assume that the halves have equal standard deviations, an assumption of the Spearman-Brown formula[1].

$$\text{Reliability} = 1 - (1+\beta)^2 / 4\beta * \sigma^2_{(a-b)} / \sigma^2_{(a+b)} + (1-\beta)^2 / 4\beta \qquad (1)$$

where $\beta = \mu_a / \mu_b$, the ratios of the means of the two subsets. In this formula, the major factor that reduces the reliability below 1.0 is the mean variation of the difference between the scores on the even and odd collections of problems, $\sigma^2_{(a-b)}$.

Testing Validity

Validity relates to the meaning of the scores and the ways we use scores to make decisions (American Psychological Association, 1985). Validity addresses the issue of how well do these scores reflect the physics achievement. One way to empirically evaluate validity of the CyberTutor data is to study its "predictive validity", its ability to predict some subsequent performance. The correlation coefficient between prediction and subsequent performance now becomes the validity coefficient.

The Value of Electronic Homework Tutor as an Assessment Instrument

Reliability of CyberTutor

The reliability method was applied first to the MIT 8.01 final exam for 2001. Figure 1 (left panel) shows some lack of consistency between the performances on the two subtests in the Final exam. This reflects the error on the two subtests: they covered the same material, but random errors are considerable. Of course, adding the two halves together reduces the relative size of the error and results in reliability of 0.85 as computed from (1). In the same way, we computed the reliability of the 12 weekly tests resulting in a reliability of 0.87. The reliability of these tests, 0.85 and 0.87, is a moderate reliability in a test. Generally reliability above 0.90, typical of ETS[2] tests, is considered good for a test in education and behavioral sciences (Manson & Bramle, 1997). For example, in the case of the final exam, its reliability means that 85 percent of the variance in the observed scores is due to true score variance. The error causes 15 percent of the observed variance. This 15 percent error will offer, lead to a misdetermination of who should pass and fail as we discuss later.

If someone is highly skillful, he generally makes fewer errors and takes less time to successfully complete a task than a less skilful person. Moreover, any individual has the option to work more quickly at the expense of making more errors or vice versa. For the electronic tutor, we developed an assessment algorithm that depends on the number of right responses and hints, subparts, and number of solutions requested. We also included additional variables (time and wrong answers) as well as all other variables available from the log of each student's interactions with CyberTutor including among others, number of problems worked, etc. We call this assessment algorithm the "Enhanced CyberTutor Assessment"

The CyberTutor algorithm is computed from the even problems and the odd problems for each student (Figure 1, right panel). The curvature indicates a small excess of easier problems in the even group. The reliability from (1) of the combined assessment is 0.9976. This is a fantastic improvement over the final examination and weekly tests. That means that 99.8 percent of the observed variance in scores is due to true score variance. Overall, it has 62 times less error than final exam and 58 times less error than the all weekly tests together. It provides nearly error-free assessment.

---

[1] Spearman-Brown Reliability = 2 * [correlation (Odd, Even)] / [1 + correlation(Odd, Even)]

[2] Educational Testing Service, e.g. tests: GMAT, GRE, TOELF and PRAXIS.

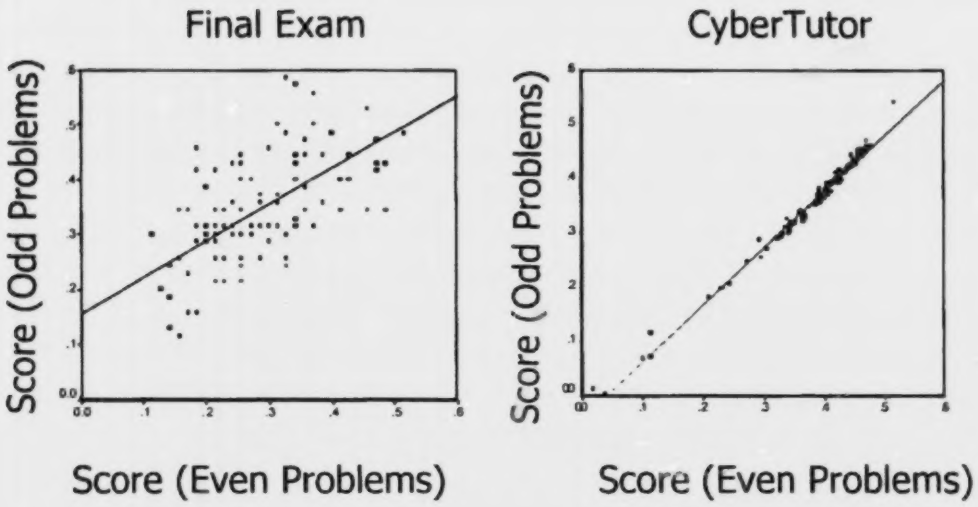

Figure 1: Grades of each individual student on the two subtests (odd -y axis - and even – x axis), comprising the CyberTutor and MIT 8.01 Final Exam in 2001.

Table 1 shows the differences among Final Exam, Weekly Tests and CyberTutor. The Enhanced CyberTutor algorithm shows higher reliability than the other tests. In addition, by eliminating marginally discriminating problems[3], we were able to increase the reliability to 99.92 percent. We called this "CyberTutor -" (the negative sign indicates that we took out all negative discriminating problems). "CyberTutor -" has 183 times less variance than the final exam. Table 1 also shows the difference of the variance per unit of assessment time The "CyberTutor -" assessment has over an order of magnitude less error variance per time than the final in this regard.

Table 1: Summary

	Reliabilities	s^2_e / s^2_t per unit time	s^2_e / s^2_t	s_e / s_t
Final exam	0.85	0.011	0.17	0.42
Weekly tests	0.873	0.014	0.144	0.380
E. CyberTutor	0.9976	0.0024	0.0024	0.049
CyberTutor -	0.9992	0.0008	0.0008	0.028

The final exam, which was carefully developed, contains so much error that 1/4 of the students assigned failing grades should has pass, and an equal number of students who should have failed are assigned a passing grade. Thus, for every two students who took the final exam one was misdiagnosed. A similar case occurs using weekly tests.

To see how this arises, look at Figure 2, where failure is set at one standard deviation below average, which fails 16 percent of the students, the typical failure rate for 8.01 course. The dashed line shows the true skill distribution inferred from the measured error and the observed skill distribution (heavy line), which is slightly broader. The number of students failed versus their true skill level, is indicated by the small curve centered on skill = 40. (The width of this curve is very nearly the width of the error.)

---

[3] By performing item analysis using item discrimination. It measures how well an item distinguishes between the students who understand the content universe if the test well and those who do not.

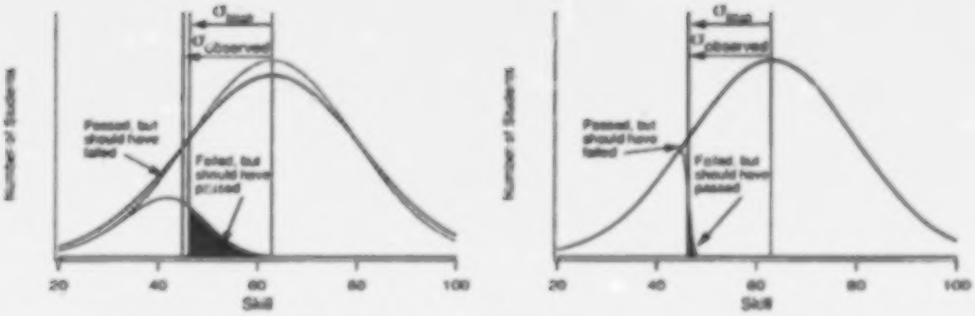

Figure 2: Fairness in the Final Exam versus CyberTutor

Below skill = 35 the failed students and the true skill distribution were coincident, indicating that all students whose skill is this low fail. Failed student curve drops well below the true skill distribution between 35 and 46 (the selected true skill for passing) indicating that some students (lighter shaded area) whose ability is below passing will pass. The distribution of failed students does not drop immediately to zero above true skill = 46, these (darker shaded area) whose true ability is passing, will fail the test.

If the much more accurate Enhanced CyberTutor Assessment were used to set pass-fail instead of the final exam, only 1 percent of the students failed would be misdiagnosed (Figure 2, right panel). In a class of 100, only one student would be misdiagnosed, and his true skill would almost certainly lies only 1 or 2 points away from the pass-fail line.

Validity of CyberTutor

The skill profile can be used to predict each student's grade on a standard test. As a first step in this direction, we developed an algorithm to predict students' grades on the "adjusted" MIT final exam. The adjustment reflected the findings from item analysis that both exam questions concerning angular dynamics were poor measures of overall skill. It is well known that many students "hit the wall" of misunderstanding here, and while we believe that an examination of CyberTutor data concerning angular dynamics would improve our predictive ability on these problems, it was cleaner to eliminate them for this study of validity.

The final prediction (Figure 3) yields a value for r, the predictive validity coefficient, of 0.71, which is highly statistically significant[4]. In fact this correlation coefficient would be higher were in not for the 15% unreliability of the final exam. This suggests that the "real" validity coefficient is around 0.77. This level suggests that a variant of the "Enhanced CyberTutor algorithm" would enable us to predict the students' skills with less error than a one-hour test such as a midterm could determine it.

We are optimistic that a prediction based on a detailed skill profile instead of the overall performance could do considerably better at predicting the final exam scores and conclude that CyberTutor as a measurement instrument is not only extremely reliable but also has significant validity. Indeed there is every reason to believe that it would give a better indication of students in trouble at midterm time than the midterm itself.

In this section, we have begged the question of the validity of adopting the final exam as a criterion of validity (e.g. only about 1/4 of the final exam involved conceptual questions). In the future we hope to use the performance in the subsequent required physics course as another measure of validity.

---

[4] The minimum value of r required to be statistically significant at the 0.05 levels a sample size between 100 and 1000 is 0.197 (Hopkins and Glass, 1978 p. 409).

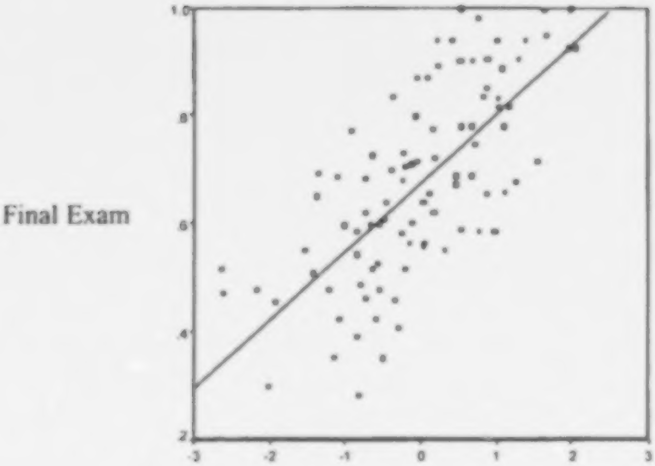

Figure 3: Prediction of scores on Adjusted Final Exam from CyberTutor data, r = 0.71. The horizontal axis is deviation from CyberTutor prediction in standard deviations

Discussion

We have shown that a web-based electronic homework tutor collects data that enables an assessment and tutoring and gives us a better way to deal fairly with students' capabilities. CyberTutor provides objective measurements on which educational decisions can be based. It can provide means for improving and enhancing feedback, motivation, and over learning.

The dramatic reduction in the variance of the error results from combination of three factors. First, the typical student interacts with CyberTutor for at least 48 hours per term, 16 times longer than the 3-hour final exam and 10 times more than 12 weekly tests together. This reduces the error variance due to the general statistical rule that the variance of error approximate 1/T, where T is the total time of the measurement.

Secondly, by considering requests for hints, solutions, and importantly the number of wrong answers and the time the student takes to complete each part of the problem, CyberTutor can make a more reproducible determination of the student's skill on a problem. Lastly if a problem is too difficult for the student as presented, CyberTutor's hints and spontaneous responses to wrong answers systematically adapt the difficulty of the problem to the student's skill level, and the CyberTutor assessment algorithm accurately determines that level. In contrast, too difficult written problems provide only an upper bound on the student's skills.

Tutor-based assessment has such low error that it is capable of providing accurate assessments on a number of pre-selected topics providing the detailed skill profile. If we took 20 topics – say the major topic of the 13 weeks of the course plus 7 foundational topics; the assessment on each topic would be twice times as reliable as the overall assessment of the current final. Even if we increased the skill resolution to include each of the major weekly topics (i.e. perhaps 180 topics) the variance on each would be small enough to identify those students requiring immediate assistance on a particular topic. By basing the assessment on a more careful analysis of wrong answers (many wrong answer reflect omission of a particular step or reflect use of a particular wrong assumption rather than just a careless error) we project that we can improve the CyberTutor assessment sufficiently to measure skill across this fine grid with the accuracy that the current final determines the overall skill of the students.

Abstract: A number of projects over the past decade, in a range of educational contexts, have sought to link forms and patterns of communicative interaction to improvements in knowledge, conceptual understanding and reasoning skills. These initiatives have produced dialogue models, methodologies for developing these in ways that lead to the design of dialogical elearning systems and empirical evaluations that have implicated the role of context in effective educational interaction. We don't, for example, "argue and discuss with anyone, about anything, at any time". Hence, the nature and characteristics of online communities have emerged as critical factors in designing educational discourse that exploits developed models and implemented systems. This paper will review a selection of work on dialogical approaches to learning, dialogue design, system design and learning communities before discussing the possibility of an integrated model for e-learning discourse, which accepts that learning is, ostensibly, a social process.

Keywords: Human-Computer Interaction, Instructional Design for eLearning, Learning Communities.

1 Vygotsky: linking dialogue processes to cognitive change

Vygotsky's (1978) theory of the development of higher mental processes can provide a foundation and inspiration for approaches to elearning that emphasise the necessity for collaborative, argumentative and reflective discourses. Although he conceived learning as an instructional process aimed at 'transforming the mind of the child into that of an adult', nowadays it is accepted that his ideas can equally apply to any relevant situation involving a learner and a more learned other[1]. This more learned other may be a teacher or a more capable student—which is often the case in higher education settings. Similarly, his theory is not bound to the 'traditional' concept of a school, but can be applied more generally, to online and other learning communities.

Vygotsky draws a clear distinction between lower level mental processes, such as elementary perception and attention, and higher level mental processes that include verbal thought, logical memory, selective attention and reasoning. He argues for a qualitative distinction between these two levels of mental performance, because unlike lower level activity, the higher level is: mediated through cultural symbols and tools; self-regulated rather than bound to a stimulus context; social in origin; and, the result of conscious awareness rather than an automatic response.

Critical in distinguishing higher and lower level activity is the qualitative developmental transition that occurs when language, or any other signification system, is internalised to operate as a mediating factor between environmental stimuli and an individual's response. This mediation *transforms* the lower level activity by *lifting it onto a higher plane* and can be achieved through the application of material or psychological tools. Further, in using such tools we become conscious and in control of our mental activities. However, Vygotsky considered language to be the most interesting and powerful of these semiotic mediators and the primary tool for thinking. He claims that these higher mental functions originate in the social, and development proceeds 'from action to thought' and therefore communication and social contact are essential. It is through the communicative process that external signification systems conveying interpersonal communication become internalised to operate as intrapersonal psychological tools that *transform* mental functioning. In other words, internal language and thought are transformed from the 'outside'. This idea is critical to Vygotsky's notions about conceptual development and the evolution of linguistic meaning as we develop our higher level mental processes.

---

[1] For brevity, henceforth, we will use the word 'tutor' in this paper to refer to the person that is considered 'the more learned other', who may be a teacher or a more capable student.

The primary theoretical construct introduced by Vygotsky for 'engineering' this conceptual change is the zone of proximal development (ZPD). According to Vygotsky (1978), the ZPD represents the place where the student's empirically rich but disorganised spontaneous, or contextual, concepts meet with the *systemacity* and logic of the tutor's reasoning. It is:

"...the distance between a child's actual developmental level as determined by independent problem solving and the higher level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers." (Vygotsky, 1978, p. 86)

Through tasks, exercises, discussions and dialogue within the ZPD, the weaknesses of the student's spontaneous concepts and reasoning are made explicit and compensated for by the strengths of the tutor's scientific conceptions and reasoning. Thus, in performing the task, the student 'appropriates' the more mature, scientific conceptualisations and becomes socialised into the expert practitioner's knowledge and approach to particular problems, subsequently operating as a more expert practitioner themselves.

The notion of the ZPD is also a positive and powerful paradigm for evaluating and improving the teaching-learning process in cooperative contexts. Failure to complete a task successfully can be evaluated in terms of what 'extra' should be introduced to improve the ZPD, instead of simply assessing a 'failure' in performance.

2 Activity theory: relations between the learner and their context

Activity theory is a development of Vygotsky's (1978) work that provides a framework for learning and development that accepts that meaning arises and evolves during interactions that are influenced by the social relations within a community of practice. Or, 'you are what you do' (Nardi, 1996, p.7) in a natural context that is influenced by history and culture. Hence, human practices are conceived as developmental processes 'with both individual and social levels interlinked at the same time.' (Knutti, 1996, p. 25).

An activity is considered the minimal meaningful context for individual actions, which means they are not rigid and static, but continuously changing and developing. These activities contain various artifacts, such as signs, methods, machines and computers, that serve as mediational tools to facilitate the operationalisation of conceptions in ways that lead to 'higher levels of thinking'. In achieving this, the mediational processes involving subjects and tools are directed towards objects, or objectives, and in transforming the objective into an outcome there is motivation for performing the activity. The addition of another 'level' that links the subject and the community and the objectives and the community is also included to complete the basic structure of an activity (Engestrom, 1987). Here, the relationship between subject and objective is mediated by tools, the relationship between subject and community is mediated by rules, and the relationship between objective and community is mediated by the division of labour. Therefore, this framework is essentially holistic. It emphasises relationships between interactions, processes and outcomes and the relevance of social conditions, such as a shared enterprise and the need for mutual engagement of conceptualisations. Therefore, the relevance of conceptual similarities and differences and changes and developments over time are taken into account in the design of mediated learning activities.

3 Discourse analysis and dialogue designs

Given that theories of learning have implicated dialogue as being central to shaping conceptual development, there is a need to further examine the features that make educational dialogue effective in ways that inform the development and use of systems that support e-learning. Work investigating natural educational dialogues that aim to change student conceptualisations in a variety of situations, have produced some consensus as to the roles, strategies and speech acts (sets of moves) which are likely to be important. For example, using the DISCOUNT Discourse Analysis scheme (Pilkington, 1999), which includes Exchange Structure, Move

(Speech-Act) and Rhetorical analyses, it is possible to determine which participants are active in dialogue and how. DISCOUNT has been used to give insights into collaboration in natural and CMC dialogue contexts (de Vincente, Bouwer & Pain, 1999; Pilkington, Treasure-Jones & Kneser, 1999). From these and similar studies there is evidence that 'successful' exchanges are more likely to include clarifying, challenging, hinting and justification moves.

A more direct approach to linking discourse analysis to system design has been proposed by Ravenscroft & Pilkington (2000), who developed the methodology of *investigation by design* (hereafter IBD). This combines discourse analysis and dialogue game techniques (e.g. MacKenzie, 1979; Walton, 1984; Ravenscroft, 2000) to specify formal dialogue models that can me implemented as intelligent and collaborative e-learning systems. A central tenet of this approach is to take some of the features of successful dialogue—as yet not fully proven to be effective—and actively design them into interaction scenarios aimed at supporting learning. Once these models have been developed, we can evaluate their effectiveness, and systematically vary the roles, strategies, tactics and moves adopted to further explore the utility of these features in guiding learners towards more systematic reasoning. Within this IBD scheme, we use the DISCOUNT (Pilkington, 1999) scheme to develop dialogue models specified as dialogue games. A major advantage of the dialogue game approach is that it allows us to incorporate rules and constraints into the design of communicative interactions that are consequently structured and managed along the lines we prescribe. Therefore, these systems can act as powerful cognitive and mediational tools that guide the dialogue and lines of reasoning in ways that lead to improvements in individual or shared knowledge and understanding.

Research investigating and examining the suitability of this approach, that has been ongoing for the past ten years (see Ravenscroft, 2001; for a review), has shown that dialogue game theory can be used as a software design paradigm for types of computer-mediated and computer-based argumentation dialogue in educational contexts. Here, the notion of a game is used to characterise and specify discourse in terms of the goals of the interlocutors (e.g. the elaboration of knowledge, the co-elaboration of knowledge, supporting or winning an argument), the relative roles of participants (e.g. inquirer, critiquer, explainer) and the types of dialogue tactics and moves that are performed (e.g. Assertion, Challenge, Withdraw). Also, rules govern the types of moves available to participants, the effect these have on commitment—to beliefs—and issues of initiative and turn-taking. Note that, in focusing on pragmatic level knowledge, these projects have not needed to directly address issues of semantic and syntactic level natural language processing and generation that have been examined by Pilkington (1992) and Pilkington & Grierson (1996). Other research has demonstrated how dialogue game theory can represent a range of dialectical discourse genres (Maudet & Evrard, 1998; Moore & Hobbs, 1996), include multimedia features (Moore, 2000) and be adapted to take account of multi-user polylogues (Maudet & Moore, 2000).

4 System designs: cognitive tools and intelligent dialogue

Projects adopting the approach above have produced a number of successful designs. They have shown that a model of collaborative argumentation—a *facilitating* dialogue game—supports and stimulates conceptual change and development in science (Ravenscroft, 2000; Ravenscroft & Matheson, 2002). And a model of fair and reasonable debate—a DC dialogue game—can be used to teach generic reasoning skills for debating controversial subjects (Pilkington, *et al*, 1992; Moore, 1993). The former dialogue game has been implemented in the 'intelligent' computer-based dialogue system called CoLLeGE and the latter model has been implemented in the DIALAB computer-mediated argumentation system, that structures fair and reasonable debate. Another project called CLARISSA has used dialogue games to implement a computer modelling 'laboratory' for investigating collaboration (Burton, Brna & Pilkington, 2000).

However, in evaluating and testing some of these dialogue games (Ravenscroft & Matheson, 2002; McAlister, 2001), the relevance of the broader, socio-cultural context is becoming increasingly apparent. So, to integrate these dialogue game approaches within e-learning contexts where they will function optimally, we will first need to understand and consider the appropriate 'conditions' for these discourses, as we cannot hold a serious and engaging educational dialogue 'with anyone, about anything, at any time'. One current project is integrating a dialogue game for critical discussion, realised through a structured interface—of sentence openers and preferred moves, within a broader framework for educational conferencing and moderating (Salmon, 2000). Thus linking a cognitive tool with a framework that defines the socio-cultural context in which it should be effective. However, preliminary findings from this project are further emphasising the need to better conceptualise and design for the community and contexts in which educational discourses operate. In brief, we need to investigate, examine and, where possible – design, appropriate learning communities if we want to support effective e-learning discourse.

5 Learning communities and cooperative learning

According to Preece (2000) 'The internet has given rise to a new community model of communication' (p xii). Currently, however, there is little agreement on what this model actually is, how we can conceptualise it, or how it can be operationalised and exploited for educational purposes. Preece (2000) herself argues for Community-Centred Development (CCD), that accepts the sociology and social psychology of community development and maintenance, putting the 'community' firmly at the centre of the design process in the same way that Norman (1986) conceived the 'user' as central. Within this scheme she points out that we need to support the evolution of communities, design for usability and plan for sociability. This approach seems to fully accept that learning is, essentially, a social process, but raises a crucial question about whether we can actually build online communities that truly satisfy the necessary social conditions for effective, and often dialectical, discourse interactions. Or, putting this another way, can we be sufficiently social online to have meaningful conversations, discussions and arguments that lead to conceptual change and development?

The recent work of Wenger (1998) on 'Communities of Practice' considers meaning, along with learning and identity, as important features in the educative process. This theory of learning, that is particularly aimed at the work-place, holds that:

'...engagement in social practice is the fundamental process by which we learn and so become who we are. The primary unit of analysis is neither the individual or social institutions but rather the informal "communities of practice" that people form as they pursue shared enterprises over time.'

Central to this notion, inspired by Lave and Wenger's (1991) work on 'situated cognition', is that these communities have knowledge about practice embedded within them, and therefore learning occurs through legitimate entry and participation within the community. Or, 'Learning is a process that takes place within a participation framework, not an individual mind' (Lave & Wenger, 1991, p 15). Wenger (1998) argues that effective communities of practice are characterised by mutual engagement, joint enterprise, shared repertoire and the negotiation of meaning in practice. Whilst this theory has been readily adopted by the business community, successful realisations in e-learning have been limited, with a few exceptions (e.g. McConnell, 2000). There can be difficulties in operationalising these key concepts within the design and operation of online communities and communication. For example, there is a problem mapping some of the features to desired discourse practices. Whilst we obviously want to promote features such mutual engagement, shared repertoire and negotiation of meaning, other aspects such as joint accountability, diversity and partiality are not necessarily appropriate in most educational contexts—except, perhaps, informal learning (for the latter two). In brief, it is not yet clear how to design, develop and maintain a community of practice supporting engaging e-learning discourse. Nevertheless, Wenger's work has provided a valuable 'conceptual resource' of socio-cultural features that should be considered when developing and designing communications in context.

McConnells (2000) work focussing on "Implementing Computer Supported Coopreative Learning" (hereafter CSCL) is one of the few practical approaches that considers Wenger's work, as he emphasises the role for socially oriented theories of learning (e.g. Vygotsky, 1978; Lave & Wenger, 1991). He proposes six design features for promoting and supporting cooperative learning: openness in the educational process (the learning community); self-determination in learning; having a real purpose in the cooperative process; a supportive learning environment; collaborative assessment of learning; and assessment and evaluation of the ongoing learning process. And he presents a specific design for a CSCL system that is successfully implemented in a UK higher education setting. The emphasis here is quite 'high level', being placed on learning management and organisation that supports CSCL, or the conditions and issues for cooperative learning in general. Whereas 'lower level' questions, such as whether the discourse processes that are fostered lead to genuine improvements in knowledge and understanding remain largely unanswered in any systematic way. Nevertheless, this work makes a useful start in considering social processes in the design and management of computer-mediated activities, and McConnell himself freely admits to the state of research and development in this field:

BEST COPY AVAILABLE

"CSCL is an idea that helps surface questions about the role of technology in learning, and about the nature and purpose of learning itself" (McConnell, 2000; p 2).

6 A synthesis: towards an integrated model for designing e-learning discourse

This paper has argued that effective e-learning requires high quality educational discourse, that leads to, at the least - improved knowledge, and at the best – conceptual development and improved understanding. We hold that this is possible if we adopt a sophisticated approach to e-learning design that accounts for necessary relationships between cognitive changes, dialogue processes and the communities, or contexts, for learning. Or, putting this another way, we need a socio-cultural framework for cognitive change, that includes motivational and affective factors. Thus far, work on developing dialogue models and system designs linked to cognitive change and development has been somewhat limited but successful, and necessitated at least ten years of research and development. But, at least, we now have a reasonable idea about what counts as patterns of good educational discourse, and how we can design systems that can effectively mediate the desired dialogue processes, in ways that, hopefully, lead to the internalisation of improved reasoning and dialectic processes. However, the key questions at the moment include: how can we design or develop the social conditions and communities that give rise to the dialogue models and discourse practices that are desired in e-learning contexts? What are the most optimal group characteristics, in terms of size and profile for example? Can we establish 'preconditions', in terms of learner characteristics and settings that will favour high quality educational dialogue?

So, the next step must be to investigate and examine e-learning communities to develop a better conceptualisation of how and why they operate successfully, paying particular attention to motivational and affective issues and factors. This should then provide the basis to either harmonise the operation of our dialogue models within existing community practice or, more prescriptively, to develop communities that are aimed at supporting high quality collaborative and dialectical e-learning discourse. Hence, we are currently developing methodologies for investigating learning communities in a number of projects that include traditional and informal e-learning contexts.

To conclude, we need to cultivate effective e-learning communities, emphasising shared interest and enterprise, and other motivational aspects. Within these communities, we can then stimulate, structure and manage high quality educational discourse that fosters collaboration, critical discussion and argumentation. We will then be able to investigate the link between these communicative practices and improvements in knowledge and understanding, because we will have to truly support the mutual engagement of conceptualisations to realise the co-elaboration of knowledge and understanding that corresponds to effective learning. Currently, we are making reasonable progress, given that work on how to develop, maintain and manage online communities is itself both new and complex. But we cannot avoid the challenge to make e-learning engaging and ostensibly social, because very few citizens want to or can learn alone.

Learning Objects – Instructional Metadata and Sequencing

Giselher Redeker

giselher@ammma.de

Abstract: The main focus of current discussions within the standardization process of Learning Technology is on economical opportunities and technical aspects of so called learning objects. Surprisingly little discussion is about the instructional or didactical issues. The purpose of this paper is to conceptualize a Taxonomy of learning objects for the facilitation of reusable instructional navigation patterns.

Introduction

At the dawn of the 21st century the industrial society is being influenced by dramatic technological development which calls for continuous actualization and advancement of peoples' know-how and capabilities in order to keep companies and economies competitive. Slogans such as "Lifelong Learning" and "Learning on Demand" verify the tendency of changing forms of learning, media, and communication as well as the inherent transformation of an industrial society into an information society.

The classical résumé - school, apprenticeship, university, career, and retirement - has therefore been increasingly challenged. Whoever wishes to be successful on the job market must continue to educate themselves in a focused manner - further education has thus become more and more a basic human need.

This basic need is, however, still faced with many barriers: training is expensive and time consuming, it often only conveys overall views and relies upon a particular time and place. In addition, it cannot be optimally adapted to individual needs as the interests of all participants must be taken into account.

The Vision - a marketplace of knowledge and education

While considering the above, imagine it was possible to access a potentially endless amount of learning material - presentations, videos, learning programs by various suppliers - right from one's own working place, to participate in training courses and classes on the other side of world. A global market of further education without any access limitations whatsoever, available to anyone anywhere, combined with the opportunity of contacting other pupils or tutors. A marketplace in which public and private institutions both compete with and complement one another, the result being effective and personalized further education - moving away from predetermined career options to individual qualification profiles.

The current situation

Internet and the World Wide Web (WWW) respectively offer ideal conditions for such a vision: they are globally available, multimedia, accessible to everyone, and also open up new opportunities in communications and cooperation. They thus allow the combination of varied further education offers ranging from simple text documents to interactive virtual classroom training, making them available to any location on Earth.

In this sense, the WWW is becoming the technological basis of knowledge globalization, a universal library accessible worldwide. At the same time, however, major problems arise in conjunction with a flexible usage of this worldwide knowledge for educational and further educational processes. Some examples include the consistency of courses already in existence, the retrieval of relevant and significant information regarding the respective thematic and didactical context as well as usage rights and payment.

Metadata, data which supplements existing information in the web with information on resources (based on additional or metainformation), illustrates one way of dealing with these problems.

Metadata is thus information *about* the resources themselves and should characterize the knowledge modules in such a way so that they can be found more easily in a given context.

Standardization Initiatives

Against this backdrop numerous standardization syndicates have been founded during the last few years. Their goal has been to define open technical standards for computer supported learning environments and education products and their characteristic metadata. The most important initiatives are the Aviation Industry CBT Committee (AICC)[1], the Instructional Management Systems Project (IMS)[2], the Alliance of Remote Instructional Authoring and Distribution Networks for Europe (ARIADNE)[3], the World Wide Web Consortium (W3C)[4], and the Advanced Distributed Learning Initiative (ADL)[5].

expandable standard.

Within these groups the main focus is on the financial opportunities that may arise, but surprisingly there is scarcely a discussion about the didactical or instructional design implications of learning objects (cf. Wiley 2002).

Consecutively I will try to conceptualize an approach for didactical sequencing of learning objects based on a specific set of educational metadata and thereupon synthesized generic sequencing strategies.

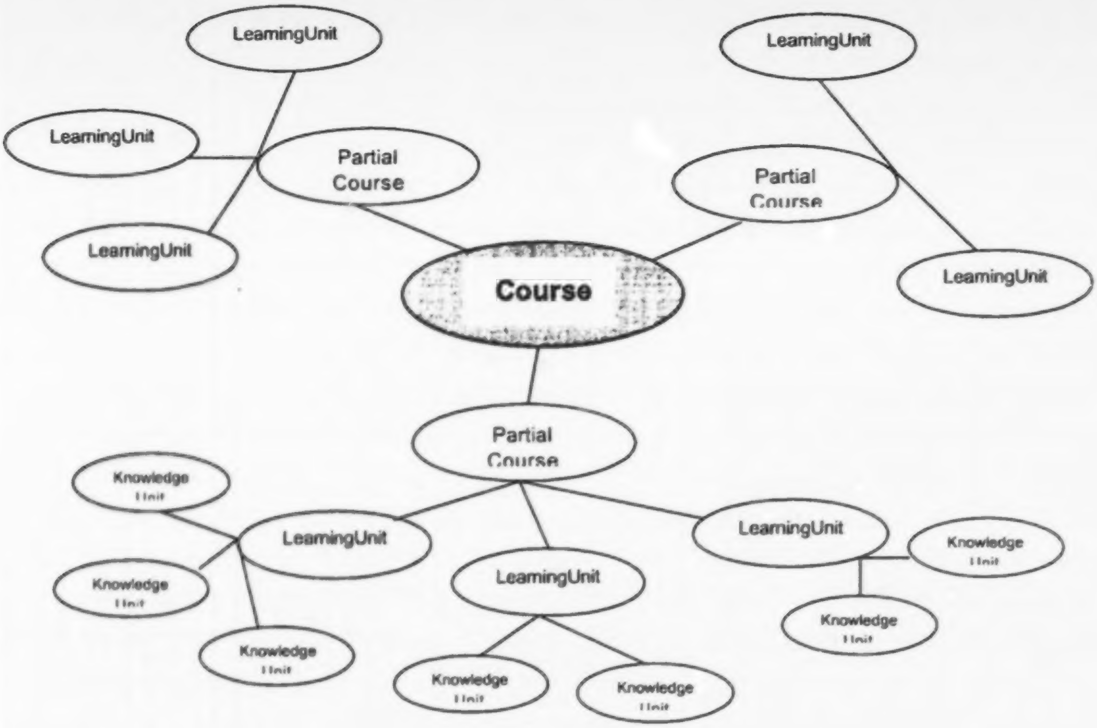
The goal is to develop a domain specific ontology for the educational science field capable of typifying teaching and learning material.

Learning Objects

In order to guarantee an optimal maintenance and reusability of contents, object oriented approaches are applied to the maintenance of multi-media teaching and learning material. Reusability, adaptation, and composition mechanisms are therefore employed to structure knowledge contents and so-called **learning objects** (LO) are defined. A learning object reduces the knowledge of a specific theme to its most essential unit. LOs may be divided into even smaller LOs. At its most basic level, a learning object is made up of several knowledge units (KUs) which may consist of texts, audio and video presentations, or animation. At this point the problem of granularity of learning objects arises. Following Wiley (2002, p. 10) "the decision regarding learning object granularity can be viewed as a trade-off between the possible benefits of reuse and the expense of cataloging. From an instructional point of view, alternatively, the decision between how much or how little to include in a learning object can be viewed as a problem of scope. While reality dictates that financial and other factors must be considered, if learning is to have its greatest chance of occurring, decisions regarding the scope of learning objects must also be made in an instructionally-grounded, principled manner."

A heuristic approach helps to balance between economical and instructionally-grounded criteria: The most basic learning object is understandable on its own and coherent, which means without references to other learning objects.

Combination of learning objects leads to the following hierarchy of learning objects:



LearningUnit
LearningUnit

Knowledge Unit

Figure 2: Hirarchy of learning objects

Hierarchy of learning objects

Course

Courses are defined as a sequence or network of learning units. Courses may - especially considering their reusability in other contexts - be divided into smaller, partial courses. A course encompasses about 30 to 60 hours of active learning time (ALT).

Partial course

Being containers, partial courses can comprise learning and knowledge units as opposed to learning units, which are solely made up of knowledge units. Partial courses are primarily designed as containers for learning units and should therefore not solely be made up of knowledge units. A partial course encompasses about 3 to 6 hours of active learning time (ALT).

Learning Unit

Learning units[7] are containers for thematically related knowledge units. Learning units are self-contained and can be, for example, reused in another course. The learning units' structure and order are defined as the macrostructure of the learning environment.
One learning object encompasses about 20-40 minutes of active learning time (ALT).
Learning units can be classified according to a three-tier thematic outline into fields (highest level), areas

---

[7] The definition in this context is based on essays by Merrill (no year given) who speaks of so-called knowledge objects in conjunction with his instructional-transaction-approach.

BEST COPY AVAILABLE

(second level), and themes (lowest level).

Using learning units makes it possible to easily exchange contents or to integrate them by combing them with other learning objects to make a new system. In this way, a high degree of exchangeability, expandability, and adaptivity can be achieved on a whole. Isolated knowledge pertinent to a particular theme can thus be more easily reused. In addition, the translation of learning environments into different languages based upon the independent management of media elements such as texts and sounds is notably eased.

In order to be able to make flexible and meaningful (re)use of learning objects in different (learning) contexts, at least three different types of knowledge objects must be present: an "orientation knowledge" object, an "explanation knowledge" object, and an "action knowledge" object. Practically speaking, a learning unit is has to have a good deal more knowledge units in order to meaningfully and cohesively portray a thematic subject. Representing a knowledge unit in several different media is, for example, very useful.

Knowledge unit

Knowledge units are the smallest elements of knowledge. Knowledge units make up the components of a learning unit within which they can be flexibly combined. As opposed to a traditional learning system and a "tightly wired" hypertext, they can be combined in any arrangement desired. The respective structure and order of knowledge units within a learning unit is defined as the learning environment's microstructure. When defining the size of a knowledge unit it is assumed that it is no larger than one monitor sheet, or, in regard to videos or mini-CBTs, it should not be any longer than 2-4 minutes of active learning time (ALT).

Within this framework, a knowledge unit is clearly defined according to the following dimensions:

	Receptive Knowledge Units	**Interactive Knowledge Units**	**Cooperative Knowledge Units**
Thematic Dimension	Three or more tier thesaurus		
Competence Dimension	Bloom's Taxonomy (possibly refined)		
Media Dimension	Ontological outline of presentational media	Ontological outline of interactive media	Ontological outline of communications media
Knowledge Dimension	Ontological outline of type of knowledge answers to questions	Ontological outline of types of tasks / filling out blanks	Ontological outline of forms of cooperation (Knowledge communication)
Relational Dimension	Thematic relation (didactics for guided tour)	Integration in learning object with didactic relations (didactics belongs in this context)	Thematic relations in regard to cooperation themes, otherwise didactic relations

Figure 3: Typing-Dimensions for Knowledge-Units

Three different types of knowledge units can be distinguished:

1. *Receptive* knowledge units
2. *Internally interactive* knowledge units the size of the smallest interactive learning sequences (up to 5 minutes) and
3. *Cooperative* knowledge units which have no time limits and are defined by communicative tasks.

The learner's role in the respective learning objects varies:

- *Receptive learning objects* place the learner in the role of merely consuming information, i.e. he or she is receptive. The learner's activity takes place outside of the module regarding the selection of a particular module, the order of the modules, as well as the time spent on the modules.
- *Internally interactive learning objects* integrate the learner in the human-computer-interaction. The learner is either CBT guided - albeit in a mini-CBT sequence - or is given the framework of his or her activities via simulation.
- *Cooperative learning objects* demand communicative activities of the learner such as brainstorming, debating, or problem solving with other learners in a group.

Cooperative learning objects are defined as "Points of Cooperation" (PoC). A PoC is thus a passage of the learning and navigation processes in which several learners can work together on a (learning) task or work on and solve a problem together.

It can be distinguished between:

- *iPoCs* (intentional *Point of Cooperation*) if the cooperation is intended by the learning material or trainer/tutor and is integrated in the course plan during the course of navigation and
- *sPoCs* (spontaneous *Point of Cooperation*) which refer to occurrences during the course in which learners spontaneously and indiscriminately cooperate with one another.

Accordingly, sPoCs can occur at any time the learner wishes whereas iPoCs are predetermined by the course material and can only be activated at certain times.

Each knowledge unit is thus typed according to the following didactically relevant dimensions:

1. In the *thematic dimension*, meaning a didactical object is classified according to a given topic (semantic/subject didactic dimension). According to the thematic area, this typification is carried out using a controlled vocabulary in the form of a three or more tier thesaurus.

2. In the *competence dimension*, meaning an ability correlates to the didactical object (pragmatic dimension). Here we make brief use of a typification similar to Bloom's Taxonomy (cognitive, emotive, sensorimotor) supplemented by the social dimension. As the definition of competence regarding a mode of operation is problematic and a part of this information is a dependent upon the type of knowledge, it remains uncertain whether or not a typification in the competence dimension is necessary.

3. In the *dimension of media presentation forms*, meaning at least one medium exists in which the knowledge contents can be portrayed and acquired.

4. In the *knowledge dimension*, meaning as an answer to questions, as the type of tasks, or as didactically pre-structured dramaturgy of knowledge (forms of cooperation).

5. In a *relational dimension*, through which the course of acquiring knowledge can be determined.

In the following I will discuss and exemplify the didactical typification of receptive knowledge units in more detail according to the knowledge types "orientation knowledge", "explanation knowledge", "action knowledge", and "source knowledge".

Types of knowledge in the receptive knowledge units

Knowledge is understood as an answer to posed questions . The types of knowledge in the receptive knowledge units are classified according to the questions "What is there?" and/or "Is there anything at all?"

(*orientation knowledge*), "Why is something the way it is?" and "What is it if it does exist?" (*explanation knowledge*), "How can it be applied?" (*action knowledge*) and "Where is there more knowledge?" (*source knowledge*). The following is a brief description of the different types of knowledge:

2.3.1 Orientation knowledge

Orientation knowledge answers the question: "What is there?"
This deals with knowledge needed in order to understand one's world and/or a particular field without having to explain or act in a specific manner.
Orientation knowledge offers a primary sketch of a topic and its further context. It motivates further exploration and awakens interest. Scenarios, stories, and facts are especially appropriate for an orientation.

2.3.2 Explanation knowledge

This deals with knowledge which explains why something is the way it is or gives arguments which must be supported by statements and recommendations.

2.3.3 Action knowledge

Action knowledge is knowledge based upon actual human activities (practices, techniques, methods, and strategies), abilities, and skills (know-how).

2.3.4 Source knowledge

Source knowledge is knowledge about sources of information (know where). It answers the question: "Where is further knowledge?"

Outlook: Generic navigational Structures

Within this conceptual framework courses are defined as a sequence and/or network of learning units. Individual learning units are in turn made up of a sequence and/ or network of knowledge units. This hierarchy results in more complex reusability and guarantees logical learning objects (i.e. learning units).
The goal of further development is to implement so-called *generic navigational structures* based upon the hierarchy concept and didactical typification in order to support writing and learning processes.
Generic navigational structures relate to the question of how teaching contents should be sequenced, in more concrete terms, which pre-structured navigation opportunities should be presented to the learner in the learning environment.
Transparency of relationships existing between knowledge units and between learning units respectively forgoes this kind of regulated navigation.
The number of modules for a certain topic form a learning unit. The learning process within a learning unit is called a micro-process. It is – as in conventional lessons – extremely adaptive, meaning dependend upon the situation (upon learning type, communication among other marginal conditions). For this reason all modules in a learning unit are reciprocally linked to one another, otherwise the adaptivity mentioned would not exist. Partial reduction of this link complexity can be considered: for example, a single link could exist to a part of the action knowledge modules whereas all action knowledge modules are linked to one another.
Depending upon the topics, the internally complex learning units are linked according to semantic networks and/or cognitive maps (knowledge maps). This structure is called a macro-didactical structure. The main questions are: Which relationship exists between term A which, as a super-character, defines topic A' to term B, which, as a super-character, in turn defines topic B'? Which learning prerequisites lie within term C which, as a super-character, identifies topic C'? etc. These generic navigational structures are to be understood as analogue to a guided tour, as recommendations, not as strict regulations. An author giving a guided tour suggests the navigation sequence but does not make it mandatory (although this should also be possible). In the same way, the system suggests navigation structures according to certain marginal conditions. Such navigation *recommendations* could be: exemplary teaching/learning in the micro-field with a top-down-structure in the

macro-field, spiral in the macro-field, and action oriented in the micro-field, to name a but a few. Such system structures are to be seen as a didactical advice the learner can follow but does not necessarily have to.

Mental Models of E-Learning

E-learning has gone through a major reality check since the global economic downturn of the last two years. Fortunately, it has survived, unlike web-based grocery delivery and any number of other "hot" ideas for e-businesses. Some have argued that once e-learning developers work out technical kinks such as interoperability standards and security issues, the e-learning enterprise will attain even the most optimistic forecasts for changing the way people learn in the 21st Century (Rosenberg, 2001; Schank, 2001).

Setting the unresolved technical issues aside, there are three other changes that are needed before e-learning realizes it fullest potential. First, we must expand our basic mental model of what e-learning is. Second, we must improve the quality of assessment within our e-learning products. Third, we must get serious about investing in rigorous evaluation of e-learning initiatives.

Cognitive psychologists define mental models as conceptions of systems or phenomenon that we construct in our minds (Gentner & Stevens, 1983). A person might have a good mental model of how an internal combustion engine runs, but a weak one of how microware works. Mental models are important cognitive structures that influence how people react to change and solve problems. They are often based on analogies or metaphors (Norman, 1983). For example, when people first began using word-processing software more than twenty years ago, they usually thought of word-processors as analogous to typewriters. A mental model of word-processing as similar to typing worked in some ways, but failed in others, such as when novice users continued to hit return at the end of every line of text rather than relying on the word-wrap function. Today's learners, for whom typewriters are as unfamiliar as slide rules, do not suffer from such misconceptions when learning how to word-process.

People also have different mental models of e-learning, depending on their relationship to it and their experiences with it. Commercial vendors of products such as learning management systems and multimedia authoring software frequently promote a mental model of e-learning as media events using terms such as "full motion video" and "dynamic learning objects." Instructional designers are more likely to describe e-learning by referring to instructional activities analogous to traditional training events such as "presentations," "discussions," and "quizzes." Subject matter experts, by contrast, tend to formulate a mental model of e-learning as an alternative vehicle for distributing content via "electronic books" or "real time databases."

Rather than as technologies, activities, or content collections, a mental model of e-learning can be based upon the concept of "outcomes." Outcomes are achieved objectives; they are the evidence that learning has occurred, performance has changed, and results have been attained. Outcomes assessment has been a major movement in education for at least a decade, reflecting a general shift from an emphasis on teaching to a focus on learning (Huba & Freed, 1999; Marzano, Pickering, & McTigh, 1993).

In the business world, a mental model of e-learning as outcomes will encourage a sharper focus on the ultimate goals of e-learning, namely performance and results. After all, what are the ideal outcomes of e-learning if not performances tied closely to the mission and goals of the organization that yield desirable results such as greater profitability, better safety records, or larger market share?

Another benefit of thinking of e-learning as outcomes is that it forces us to consider how we will certify that the outcomes have been achieved. In other words, the nature and quality of assessment becomes paramount in a mental model of e-learning as outcomes.

New Directions in E-learning Assessment

Assessment, defined as the activity of measuring learning, is still a relatively weak component of most e-learning programs (Schank, 2001). In fact, vendors, instructional designers, and subject matter experts alike appear to struggle with conceiving of assessment as anything more than a multiple-choice test. Despite the sophisticated multimedia features of many e-learning programs, a closer look at the assessment strategies in these programs suggests that developers, perhaps limited by today's still primitive authoring systems to highly predictable algorithms, often fall back upon overly simplistic multiple-choice test items that primarily measure low-level retention of isolated facts.

This is not adequate. The knowledge workers of the 21st Century workplace are rarely confronted with clearly delineated choices from which they must select; instead they must generate original solutions to unique problems. Traditional multiple-choice tests cannot tap into the critical ability to frame and resolve ill-defined problems. Fortunately, a few good examples of alternative assessment in e-learning for business and industrial training are emerging.

In this paper, we describe one such example, specifically the innovative assessment approaches found in the e-learning courseware developed by LearnWright of Rockville, Maryland, USA (www.learnwright.com). LearnWright specializes in the development of training for regulated industries such as pharmaceutical companies. One type of e-learning developed by LearnWright is Good Manufacturing Practices (GMP) training that is mandated by the U.S. Food and Drug Administration (FDA). LearnWright GMP courseware includes a number of innovative performance assessment strategies such as:

- AUDIT CAM ("What's wrong with this activity?")
- AUDIT CVR ("What's wrong with this conversation?")
- AUDIT DOC ("What's wrong with this document?")

The screen capture in Figure 1 illustrates a typical assessment approach used in the LearnWright GMP courseware. This assessment item presents the learner with multiple comprehension and application challenges. The learner must first watch a brief video that illustrates the performance of a worker in a pharmaceutical manufacturing environment. The learner is then required to locate performance problems in the video, specify the nature of the problem, and finally, identify the specific type of GMP regulations violated in this problem. In terms of outcomes, this type of item engages multiple types of higher-order cognitive processes including classification, interpretation, abstraction, application of rules, and judgment.

Correct! Not wearing gloves is a problem. Taking samples without gloves can cause contamination of the material being sampled. The type of contamination most likely to happen would be from:

☐ particulates.
☑ microbes/bacteria.
☐ physical objects.
☐ other chemicals.

Figure 1. Virtual Audit Tool in GMP Training developed by LearnWright.

One of the distinctive features of this type of assessment is that it blends assessment with learning. In traditional training, assessments are usually distinct activities clearly separated from instructional events. For example, after trainees have attended a number of classes, they are given some sort of examination. Or, after a worker reads a given number of screens in an e-learning program, he or she is linked to a quiz. However, a major advantage of e-learning environments is that assessment activities can be embedded unobtrusively into the interactive structure of the program themselves. As described above, the assessments developed by LearnWright provide excellent examples of this approach. Learners are engaged in a series of increasingly complex problems, complete with detailed guidance and feedback. These interactive learning activities blend naturally with the virtual audit tools for activities, documents, and conversations that are integral to workplace performance.

Figure 2 illustrates how LearnWright has moved its interactive training products from a traditional e-learning model whereby instruction (usually in the form of didactic presentations) is separated from assessment (usually in the form of simple multiple choice questions) to an enhanced model whereby instruction (in the form of increasingly sophisticated simulations) is

BEST COPY AVAILABLE

blended seamlessly with assessment (in the form of Virtual Audit Tools and performance assessments). A major advantage of the approach illustrated in Figure 2 relates to "alignment," probably the most important characteristic that should be evident in thinking of e-learning as outcomes. Alignment is evident when there is a clear degree of synchronicity among learning objectives, content, the tasks in which learners are engaged, technological features, and assessment strategies. Many of the flaws in existing e-learning programs stem from a lack of alignment.

For example, consider the integration of Web resources into an e-learning course that might be offered in a higher education context. Such courses often provide access to extended digital resources such as electronic journals, real time databases, and online discussion forums that students are expected to utilize to enhance their learning. But academic developers are often disappointed by the degree to which learners actually use these and similar online resources. However, learners may simply perceive that these resources have little relationship with assessments in the course (such as writing a paper or taking a final exam), and so they "wisely" choose to target their cognitive efforts on those learning activities that they perceive as more clearly aligned with attaining the highest scores on assessments. After all, students are only human, and although course developers might wish that students will access all resources simply because of the desire to learn, they are more likely to use only the resources that have obvious links to assessments. Clarification of the alignment within e-learning courses is an important role for evaluation specialists. Unfortunately, many e-learning development teams neglect to include evaluators (either internal or external), and so alignment goes unchecked.

Assessment in e-learning programs can have multiple roles ranging from narrow, formative purposes (Did the learners master the skills to be learned in one section of the program, indicating their readiness to proceed to the next section?) to broad, summative ones (Do successful e-learners perform on the job in ways that contribute to institutional success?). The development of assessment strategies in e-learning should be guided by a common set of questions such as:

- What is the purpose of the assessment, e.g., formative (to provide information for helping someone learn) or summative (rendering a judgment of a learner's competence)?
- What is the scope of the assessment, e.g., a quiz administered within an individual module or a final assessment of learners to certify that they are ready to be awarded a license or certification?
- What is being assessed, e.g., knowledge, skills, attitudes, mental models, or higher order thinking capacities?

Outcomes come in many forms. Some are psychomotor involving specific physical skills such as the proper way to lift a box by bending at the knees. Some are affective such as the motivation to show up at work on time or pitch in when there is a crisis. Many are cognitive, ranging from knowledge of simple concepts and rules to robust mental models such as a deep understanding of Good Manufacturing Practices (GMP) within the pharmaceutical industry or the commitment to safety in any workplace.

Corporations are increasingly concerned with higher order outcomes such as problem-solving, ethics, creativity, and commitment. The latter are much harder to assess, and most authorities advocate basing assessments upon a range of indicators rather than seeking one precise measure. Instead of asking "what test should we use?," e-learning designers should ask themselves "what can we possibly count as evidence that learners have attained these higher order outcomes?" Assessments of complex outcomes such as ethical reasoning inevitably require a variety of indicators to "triangulate" them.

LearnWright has adopted the following guiding principles in developing assessment strategies for its e-learning products:

- If it hasn't been assessed, it hasn't been learned.
- The closer the assessment tool is to how the job is performed, the more valid the assessment is as a predictor of how the person will perform on the job.
- Reliable, valid, and authentic assessments serve multiple purposes:
    - improve learner performance,
    - improve courseware quality,
    - improve organizational effectiveness,
    - qualify training performance to other stakeholders (e.g., regulatory agencies and consumers), and
    - foster better evaluation.

Better Assessment Can Lead To Better Evaluation

Although the terms are often used interchangeably, assessment and evaluation actually have two distinct meanings (Worthen, Sanders, & Fitzpatrick, 1996). Assessment is defined as the activity of measuring learning whereas evaluation involves judging the effectiveness and worth of programs and products. In short, we assess people and evaluate things. The terms are often confused, perhaps because the same data can be used for both functions. An exam in an e-learning course in a professional continuing education context can be used to assess student learning and provide the basis for awarding certification. The same exam results, however, might be used to evaluate the effectiveness of a course, especially if other versions of the course are available for comparison.

Advancements in assessment strategies are being made as evidenced by the cutting-edge outcome assessments created by LearnWright described above. Although we readily acknowledge that there is other creative work being done in e-learning assessment elsewhere (Rossett, 2001;

Schank, 2001), the state-of-the-art of assessment in general is almost as weak as the state-of-the-art of e-learning evaluation.

What is the basis for this claim? According to the American Society for Training and Development, evaluation lags behind because most e-learning programs are only evaluated at the lowest level of Kirkpatrick's classic evaluation model, simply finding out if learners like e-learning (Rossett, 2001). But if developers and their clients begin to think of e-learning as outcomes, not only will assessments improve, but attention to higher levels of evaluation will follow because we shall be able to more easily address questions such as:

- Do learners master the desirable knowledge, skills, and attitudes?
- Do learners transfer their new learning to performance in the workplace?
- Does enhanced performance contribute to the bottom line such as higher profits?
- Given positive results, what was the return-on-investment for e-learning?

These are the evaluation levels that are sorely needed in the rapidly evolving world of e-learning (Reeves & Carter, 2001). Changing our mental model of e-learning to one focused on outcomes is a step in the right direction toward improving both assessment and evaluation. But more than a cognitive change is required. The e-learning industry as a whole must commit to more realistic investments in evaluation of its products. Amazing advances emerge almost weekly from the pharmaceutical field, primarily because of the extensive research and development that industry supports. For the e-learning industry to realize analogous results, we must invest at least ten percent of our funding in multiple levels of evaluation. There is no time better to start this level of investment than now.

Abstract: Online learning is coming of age in both postsecondary education and industry. The range of courses now offered online ranges from kinesiology to mathematics to complete M.B.A. programs. The growing popularity of online education has created a need to reduce costs without diminishing the value of the edification. In response to this need, an instructional technology concept commonly referred to as the "learning object" was born. This paper explores the learning objects concept, their value to an online education, as well as an applied outlook into the use of learning objects in an online environment. The paper concludes with a discussion on how learning objects can be integrated into a specific example of an online course.

Introduction

An online course often forces its creator to expend onerous amounts of time creating the course's lessons, assignments, and exams. This necessitates high time and cost investment (Rumble, 2001). By sharing similar learning materials the costs of an online course could be greatly reduced. Learning objects are a means of encouraging this type of collaboration.

Due to the promise of their innate simplicity and to their cost and time saving implications, learning objects have become one of the few concepts predicted to alter the landscape of learning in the near future. Groups from academics to multi-billion dollar organizations such as Microsoft are discussing and testing the potential impact of learning objects. Professors at Brigham Young University in Provo, Utah, for example, will be soon be able to develop, capture, and deliver learning objects through their own university wide system (South, Monson 2001). Microsoft's Learning Resource (LRM) interchange toolkit is a product geared towards developing and manipulating learning objects.

This paper discusses the rapidly growing topic of learning objects. First a plethora of 'learning object' definitions are reviewed as groundwork for a working definition of the learning object term. A brief discussion of the relationship between learning objects and other object-oriented frameworks is followed by a classification scheme for learning objects. The potential positive consequences of learning objects on an online education are then outlined. The practical applications of learning objects on an online environment are discussed with a particular emphasis on the construction of an online course and its components. Finally an example application of how to start to transform an online course to a learning-object based online course is offered.

Learning Objects in an Object-Oriented Framework

Another means of understanding the learning object term is to view them as object-oriented elements.

In the last decade or so object-oriented techniques have dominated the information technology community. This community defines object-oriented objects as "a self-contained entity that consists of both data and procedures to manipulate the data" (Tech-glossary, 2002). The object's data, also referred to as attributes, is used to represent important information about the object. The object's procedures, on the other hand, represent things that the object can do. For instance, a dog object would consist of attributes, such as furry hair and four legs, and would also be composed of procedures, such as barking.

In order to allow learning objects to be easily accessible, each learning object must have at least a title and/or author associated with it. Hence a learning object's *attributes* could consist of things such as a title and author. Since learning objects are modular building blocks, they must have the ability to be combined and separated. The combining and separating actions performed by a typical learning object are some of its *procedures*. Since learning objects satisfy the prerequisites of possessing both *attributes* and *procedures*, they are object-oriented objects.

Background

Nearly a decade ago Wayne Hodgins, a learning and informant futurist, gave birth to the term "learning objects." Hodgins coined the term while watching his children play with Lego. The plug-and-play and reusability characteristics of the parts ignited the idea of objects that, in a similar manner to Lego parts, could be used to build learning modules (Jacobsen, 2001).

Learning objects have since become an extremely popular topic. As a result there have been numerous groups attempt to provide a definition for what they believe learning objects to be. There currently exist hundreds of definitions for the learning objects term in the World Wide Web. With such a vast number of differing explanations, it can be a struggle to merely define learning objects let alone understand how to use them. It is easiest to view these definitions as a spectrum with those who view a learning object as an abstract *concept* at one end, and those who view learning objects as a *product* in the other.

At one end of the spectrum the Learning Technology Standards Committee (LTSC) characterize learning objects as "any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning" (LOM, 2000). This definition views learning objects as an extremely broad and abstract concept. By allowing any entity "referenced during technology supported learning" to be a learning object, LTSC allows most persons, places or things to fall under the learning object classification.

At the opposite end of the spectrum commercial vendors, such as Cisco, often provide more focused and product based learning object definitions. Vendors' definitions tend to encapsulate their, often proprietary but sometimes open standard, products. Cisco's Reusable Learning Object (RLO) is defined as "a sum of one or more Cisco Reusable Information Objects (RIO)" (Barron, 2000). A Cisco RIO is defined to be "any concept, fact, process, principle, or procedure" (Barron, 2000). The fact that each RLO is made up of one or more Cisco RIO's, and that learning object based solutions are implemented by Cisco's own "Converged Voice, Video, and Data Products" (Cisco Systems, 2001), demonstrates that Cisco's learning object's definition encapsulates their own products.

To avoid the trap of providing a very narrow definition that depends on a particular company's products, or of having a definition so abstract that even a single piece of paper could be considered a learning object, A learning object will be defined here to be:

> "A digital, reusable, modular, and easily accessible building block comprised of a *content* and an *assessment* component"

The digital characteristic constrains a learning object to something that can be distributed through some sort of electronic medium. The reusability characteristic ensures that a learning object may be produced once and reused many times thereafter. Since a learning object can be an online lesson, or merely a portion of it, the learning object must also be modular. The modularity characteristic implies that, like most building blocks of any sort, multiple learning objects can be combined into larger learning objects. Finally, learning objects must be easily accessible, so that it is possible to locate a particular one in a reasonable amount of time. The content portion of the learning object is meant to encapsulate the knowledge this object is supposed to teach. Whereas the assessment portion encapsulates numerous questions that can be used to assess that particular learning object's content.

Classifying Learning Objects

Attributes of learning objects such as title and author allow a learning object to be easily found. The type of information that allows us to classify and consequently find learning objects is called "Metadata."

Roberts and McGreal define Metadata as "data about data" (2001). In a library the information in the book catalog is a collection of metadata about books. A book's author, book name and publisher are all pertinent data to that book.

In order to satisfy the easily accessible characteristic of learning objects, it makes sense to provide metadata similar to a book's metadata. Currently the Learning Objects Metadata Working Group is creating standards that specify the metadata for learning objects (such as Title, Author, Version, Format, etc.). These standards will be crucial to the use of learning objects since they will allow learning objects to be effortlessly classified. Once all learning objects abide the metadata standards, individuals creating learning content will be able to find the learning objects they are searching for without difficulty.

Learning objects in online instruction

A working definition of the learning object term precedes an analysis of the importance of learning objects to online education. Typically an educational online content creator may spend countless hours building a single educational component. Using learning objects can help reduce the time and monetary costs associated with the repetitive construction of online and, potentially, face to face instruction. Learning Objects are able to eliminate costs by promoting content reuse and by allowing multiple and simultaneous access of the content. Additional positive side effects of learning objects include ease of use, familiarity in instructional content creation, and the potential for personalized instruction.

1. Content Reuse. The fundamental idea behind learning objects is that instructional designers can build small instructional components (or learning objects) that can be reused a number of times in different learning contexts. For example all first year calculus courses, regardless of faculty, have at least one lesson on trigonometric differentiation. Rather than have to create separate lessons on this topic for each calculus course, learning objects reusability characteristic allows the creation of a distinct trigonometric differentiation lesson from the same learning object. They may all use different examples to elaborate on the topic but, since the essence of the topic is the same, the same learning object can be used to provide a more rapid and cheaper instructional content construction than with typical online content construction.

2. Multiple and simultaneous access. Since learning objects are digital entities, they are deliverable over the Internet. As a result any number of people can access and use learning objects simultaneously (Willey, 2001). Time is saved since multiple and simultaneous access implies that when creating online lessons multiple content creators can access the same learning object concurrently.

3. Familiarity in instructional content creation. Reigeluth and Nelson suggest that when teachers first gain access to instructional materials, they typically break the materials down into their constituent parts, and then reassemble these parts in ways that support their instructional goals (1997). Since learning object's can be sequentially combined, the task of creating online content is a natural one.

4. Personalized Instruction: Individuals have differing learning needs, interests and learning styles; therefore they can benefit from instruction that is personalized to their needs. Learning objects can accommodate a learner's preference and style because of their inherent characteristics. In particular, learning objects' accessibility, ease of use and reusability characteristics promotes the use of differing instructional strategies to fit that of the learner's

Issues in Applying Learning Objects

How Are Learning Objects Intended To Be Used?

A surplus of techniques for creating and interacting with learning objects exists. The basic handling of learning objects is intended to be:

1. Allow access to learning objects in an on-demand fashion
2. Allow the creation and submission of learning objects

Building this type of interaction necessitates a repository where learning objects can be uploaded and downloaded. Due to the modular characteristic of learning objects discussed previously, our repository will contain learning objects of various granularity types. At the lowest end of the granularity spectrum, an *atomic* learning object is defined as a learning object that solely focuses on one topic. Higher-order learning objects differ from atomic ones in that they focus on more than one topic, and hence are an amalgamation of distinct learning objects. In the sections that follow various techniques for creating higher-order learning objects shall be explored.

An Application: Systems Analysis and Design

A senior undergraduate course in Business Administration has been offered both place-based and online for several years. Each has an identical set of learning objectives, but the delivery format differs in the Spring versus Summer and Fall offerings. Using the above definition, learning objectives could be categorized, learning objects derived, and the course offered more consistently in both formats and updated in a more modular fashion. First, an inventory of topics is outlined. A weekly lecture, for example, is typically made up of one to three topics, such as 'Introduction to Systems Analysis,' 'The Systems Development Life Cycle,' and 'Problem Finding and Problem Solving Methodologies' in a first week of such a course. Each topic is then stored separately with a series of attributes. In the systems analysis course, the attributes are:

- Text title(s) and chapter(s) (text)
- Online lecture notes (html)
- Face to face presentation file (MS Powerpoint)
- Weekly exercise outline (text)
- Discussion question(s) (text)
- Examination question(s) (text)
- Relevant WWW links (text listing)

A course outline, then, links a series of such objects into a repository. Each topic serves as a kernel to comprise an overall course, and seeds a course web site (another higher level object) which presents the elements relevant to the audience. Over time, multiple teachers could add elements, examples, and new links to each object, and objects could be used in different combinations for different audiences and related topical overviews.

Tools to Support Learning Objects

Standards for support, such as XML objects, have been touted as 'Learning Objects.' The concept is more a modularization of course elements than identification of a software or standard at this point, but certain tools will prove beneficial as this concept matures. No single standard has yet surfaced that will converge the concept of Learning Objects, but the formalization of the topic promises to standardize elements used to build support for a learning outcome.

A final caveat remains with the notion of 'art' versus 'science.' Support materials for courseware can be standardized and stored, but excellent support cannot guarantee excellent learning experiences. New examples constantly emerge, and different personalities teach with different approaches. A support repository containing categorized objects and methods, however, will offer us a language to communicate among different teachers of the same material, and build on past successes rather than reinventing the discussion each time. The concern of a single

Abstract

This paper describes key issues in conducting impact evaluations of corporate eLearning and reports the results of a study to evaluate the impact (including ROI) of an eLearning implementation by a large telecommunications company. The programme was designed to multi-skill over 1,000 Customer Service Officers (CSOs) using custom-designed eLearning courses that provided coaching as an integral element. The two critical business objectives of this initiative were to save training costs and to reduce training time. More were realized.

1 Key Issues in the Design of Impact Studies

Impact evaluation is the greatest challenge faced by evaluators of any type of educational programme (Reeves & Hedberg, in press). Not surprisingly, it is also the most neglected facet of evaluation. It is not easy to determine the impact of different learning approaches in any environment. There are invariably alternative explanations and influential factors for most findings such as marketing initiatives, new processes, economic conditions, internal company politics, and the like. Reeves and Hedberg (in press) recommend that it is appropriate to consider "impact" in terms of Kirkpatrick's (1994) Level 3 (Behaviour) and Level 4 (Results) as well as Phillips' (1997) Level 5 (ROI). Further, they advise "building a case" for the impact of an eLearning programme rather than attempting to demonstrate conclusive findings in a traditional scientific sense. Several factors that must be considered when designing an impact evaluation for corporate eLearning are described below.

1.1 Evaluation Decisions, Issues, and Questions

One of the first steps in impact evaluation is delineating the issues on which the impact evaluation will focus. Are you or your clients primarily interested in improvement in work performance? Reduction in costs? Increase in sales? Reduction in complaints? Greater profitability? Return on investment (ROI)? For each of the critical issues specified by you or your clients, you should identify potential decisions that must be made about these issues. For example, if the issue is reduction in costs, what decisions will be made concerning the eLearning programme if it can be demonstrated to have a positive impact on reducing cost? Will it be implemented company wide? Or perhaps marketed as an eLearning product for use by other companies? Once the decisions are identified, you will be able to define the specific evaluation questions that will be addressed. For example, what was the average time and cost of a customer service call before and after eLearning implementation? Or what is the morale of the sales training force in the wake of a large scale eLearning initiative?

1.2 Elapsed Time

Impact studies require that sufficient time has elapsed between implementation and evaluation in order to determine whether the programme had a lasting impact on learning. The specific amount of time is related to the nature of the learning outcomes. Changes in customer relation techniques are likely to show up in the bottom line sooner than changes in the mental models that workers have of good manufacturing processes. However, the longer the time

BEST COPY AVAILABLE

between eLearning implementation and impact evaluation, the more likely that there will be rival claimants to any positive results detected by the evaluation.

1.3 Sample

The sample size must be sufficient and representative (preferably random) for the study to yield valid results. Most impact evaluations utilize pre-test, post-test designs rather than the more rigorous control group designs. Few corporations have the time or resources to conduct control group studies, not to mention the liability issues that can arise in experimental approaches. Regardless of the design, sample sizes of at least 30 learners are recommended in most evaluations to permit the use of appropriate inferential statistics.

1.4 Instruments and Techniques

There are many different instruments and techniques for collecting impact data, including interviews, questionnaires, observation, self-reporting, diaries, and so forth. Regardless of what type of data collection instruments are used, they should be examined for reliability and validity. If feasible, unobtrusive data that is already routinely collected should be utilized, e.g., length of service calls or sales figures.

1.5 Data Collection

Since establishing direct causal links is difficult in education and training contexts, triangulation of data sources is the best approach to take. Triangulation involves seeking to compensate for the imperfections inevitable in any single type of measure by using multiple methods that may give you a clearer estimation of what you are evaluating. Other strategies for improving data collection include:

- allow anonymous responses to enhance validity;
- encourage high response rates to surveys and questionnaires;
- ensure subjects don't feel pressured to give 'expected' results, e.g. if surveys are distributed by the boss;
- even though most corporate evaluations occur "on-the-job," try to be as non-intrusive as possible; and
- include responses to both closed and open questions to maximise the amount (and type) of information obtained.

1.6 Interpretation of Results

It is a natural inclination to claim that any positive results stemmed from the eLearning, and that any negative, perhaps unexpected results were caused by uncontrollable factors. It is best to be cautious in your impact claims because of the number of other variables with potential impact that may not have been measured. It is especially important to acknowledge reliability limitations when placing a heavy reliance on self-reported, impressionistic data of the kind that is yielded by methods such as interviews and focus groups.

1.7 Secondary Benefits

Don't ignore relevant side effects and extra benefits. Even if it may be difficult to attribute something as concrete as increased sales to eLearning when other things are occurring (e.g., advertising campaigns), it may be enough to demonstrate that there are self-reported and supervisor-observed increases in morale among the sales staff.

1.8 Data for the Future

Instead of conducting isolated impact evaluations, it is better to collect data that is relevant to future planning and can be relied upon to inform future training decisions by the client on an on-going basis. You should keep any raw data in a database. This can help you plan for future course maintenance and updating as well as in budgeting.

1.9 Who Evaluates?

If possible, the credibility of your impact evaluation will be enhanced if you utilize external evaluators rather than internal members of the development team. At the same time, whenever possible, development team members should take part in impact evaluations so that they can observe the results of their efforts firsthand.

2 The Case Study

2.1 Background

This study collected data from a random sample of CSOs who completed two new eLearning courses: General Billing Service (GBS) and Wireless Data Products and Services (WPS). The sample is from the first few intakes of these courses that occurred between May and July, 2001. The total enrollment in these intakes (for both courses) was 155. The total number of evaluation participants was 77 and the two sample sizes were 37 (GBS) and 38 (WPS), with no overlap. Data were also collected from the supervisors of CSOs for each sample to determine whether they observed any impact of the eLearning courses on their staff. The primary issues of concern for the evaluation clients were saving training costs and reducing training time.

Data were collected via three questionnaires for CSOs and a separate questionnaire for supervisors (for each of the two courses). Subjects in the sample received the questionnaires via e-mail and responses were anonymous in that they were sent by and returned to an external evaluator employed by the eLearning provider, not their supervisor. The evaluator was also independent of the eLearning course development process.

The first questionnaire for CSOs had 15 items and asked respondents how often they used each of the specific tasks taught in the course (everyday, most days, occasionally, never). A major purpose of this non-threatening questionnaire was to put the subjects at ease with the study, a factor that can positively affect reliability. The second CSO questionnaire had 15 items and asked about impact. Specifically, it asked the extent to which respondents performed each of these tasks after the eLearning course in comparison with how they performed the tasks prior to the course (much better, better, same, worse). The third CSO questionnaire had 9 "yes/no" items and three open-ended items, and asked whether certain behaviours and attitudes had changed because of this eLearning. The supervisor questionnaires had six closed items and one open-ended item, and asked the extent to which they observed the impact of eLearning on their staff. The open-ended items in the third CSO and Supervisor questionnaires suffered from low response rates (14 and 10) and failed to provide any significant information that had not already been derived from the closed items.

The courses in the eLearning programme had clear and specific objectives. The tasks in a given course were all relevant to one specific kind of customer call. The calls were either about wireless data products and services (WPS) or billing (GBS). The WPS course addressed 18 tasks (or how to handle 18 kinds of calls). These tasks involved explaining, assisting, guiding, and helping customers. The GBS course addressed 15 tasks, including updating customer particulars, determining correct procedures, resolving complaints and disputes and advising or informing customers.

2.2 Results from CSO Questionnaire #2 (impact)

WPS Course

The four tasks with the highest percentages of "much better than before [eLearning]" responses follow. Three of these tasks are among the most frequently used tasks, which makes these results more significant.

- Explaining the benefits of using GPRS (56%)
- Explaining the types of equipment needed to access Mobile Office (48%)
- Guiding callers in setting up their equipment to access e-ideas on the WAP (48%)
- Explaining the kinds of equipment needed to use GPRS (43%)

GBS Course

The four tasks with the highest percentage of "much better than before [eLearning]" responses follow. That these tasks are among the most frequently used tasks makes the impact even more significant.

- Determining correct procedures for reconnection of services (63%)
- Negotiating with customers for agreement on partial or deferred payments (58%)
- Interpreting basic account and payment information from the customer profile (56%)
- Advising customers on suitable payment modes for paying bills (52%)

2.3 Results from CSO Questionnaire #3 (behaviours and attitudes)

WPS Course
Between 90 and 100% said "yes" to each of the following statements:

- I now know more about wireless data products and services than I did before [eLearning].
- I now have more confidence dealing with callers [than I did before eLearning].
- I feel I can give better answers to callers' questions [than I could before eLearning].
- I don't have to transfer as many calls to others as I did before.
- I share information with more colleagues than I did before [eLearning].
- If I need more information to answer a caller's inquiry, I know where to find it on my own.

GBS Course

- Between 90 and 100% said "yes" to each of the following statements:
- I now know more about general billing than I did before [eLearning].
- I now have more confidence dealing with callers [than I did before eLearning].
- I share information with more colleagues than I did before [eLearning].
- If I need more information to answer a caller's inquiry, I know where to find it on my own.

2.4 Results from the Supervisor Questionnaire

The supervisor questionnaire had six closed items and one open-ended item. This questionnaire asked supervisors whether they had observed the following changes in their staff after the eLearning courses. The closed items were:

- The staff seem to know more about wireless data products and services [or general billing] than they did before the eLearning
- They seem to have more confidence dealing with callers
- They seem to be able to give better answers to callers
- If they need more information to answer a caller, they can find it on their own
- They seem to share information with colleagues more than they did before eLearning

The WPS supervisors reported that 97% of their staff in this sample seemed to transfer fewer calls than before and 93% seem to have more confidence dealing with callers [after eLearning]. The two items with lowest impact were: seem to know more about wireless data (74%) and if they need more information to answer a caller, they can find it on their own (72%).

The GBS supervisors reported that 100% of their staff in this sample seem to be able to give better answers to callers than before [eLearning] and to transfer fewer calls than before, and that 97% seem to have more confidence dealing with callers. The two items with lowest impact were: seem to know more about general billing (72%) and seem to share more information with colleagues (86%).

2.5 Interpreting Results: Design Concerns

The fact that the subjects in the study were busy workers functioning in a very busy environment resulted in some constraints. For example, intrusive methods such as observation were not possible. With the relatively small samples represented in this evaluation, generalisations must be made with caution. However, the fact that the sample was chosen randomly ensured that the sample could be considered to be representative of the population as a whole.

A more serious concern has to do with the percentage of CSOs and supervisors in the samples who completed and returned the questionnaires. In this study, the response rate was 67% for the CSOs and 54% for the supervisors. However, the important evidence in this study seems so unambiguous that confidence in it is high despite this shortfall in the response rate.

That the evidence in the study comes from self-reported, impressionistic data has to be acknowledged. With self-reported data, reliability is often a concern. This might be more of a concern if the data were not so strongly skewed in a positive direction. Also, the collection of corroborative data from the supervisors of the CSOs in the sample provided some triangulation of data.

While there was no rigorous formal validation of the questionnaires, the data collection instruments were carefully designed to provide data that were likely to provide acceptable levels of validity and reliability. The focus of the items was narrow and the subjects were highly familiar with the tasks. In some evaluations, there is a concern that respondents will give "expected" or "socially desirable" responses instead of revealing their true feelings. This is always possible since a respondent could guess what a desirable response might be. The actual likelihood of this having occurred was minimised by the fact that the responses were anonymous and questionnaires were returned by e-mail to the independent external evaluator rather than to the subjects' supervisors.

2.6 Effectiveness of the eLearning Courses

Data from the CSOs in the sample studied showed that they felt they could handle customers' calls better after eLearning than they could before it. Data from their supervisors indicated that they observed the impact of this eLearning on these members of their staff.

The CSOs also reported that they:

- had more confidence dealing with customers than they had before eLearning
- can now provide better answers to callers' questions
- know more about the field they studied
- transfer fewer calls to others
- have made several other desirable behavioural and attitudinal changes.

In specific terms, the majority of learners in both classes felt that their performance had improved at least somewhat in almost every task taught. Between the two courses 33 relevant tasks were taught. In 30 of those tasks, the majority felt their performance had improved. The lack of ambiguity in the data does provides confidence in the conclusions and lessens any technical concerns we might have about reliability or return rates or self-reported data.

2.7 Business Results (ROI)

Three types of ROI results were reported: 1) cost savings, 2) training time savings, and 3) indirect savings. The savings shown below are based on a comparison between the costs of the total eLearning programme of four courses (the two reported in this paper and two more) and the costs of the "equivalent" instructor-led programme. Throughout the analysis, in order to be conservative, it has been assumed that 800 CSOs will take the programme rather than the 1,000 predicted. Total savings with the new programme were over SG$2M. Net savings, after deducting the costs for development of the new programme were SG$348,518.

ITEM		COST SAVINGS (SG$)
Staff productivity gain (a result of diminished training time)		828,800
Reduction in instructor costs		44,000
Training materials		19,200
Reduction in training room costs		280,000
Participant replacement costs (at 40% replacement)		808,960
Refreshments		63,200
	Total savings	2,044,560
	Less hardware & software costs	-80,042
		1,964,518
	Less development costs	-1,616,000
	Net savings	$348,518

The new eLearning courses required 25 eLearning days whereas the equivalent instructor-led courses required 39.5 days. This gave a reduced training time of 37%. For each day a staff member took the "equivalent" instructor-led course, she/he was away from the work site resulting in a complete loss of productivity. With the eLearning programme, the CSO was away from her/his workstation only twelve hours, and never for a full day. Except for these twelve hours, the CSOs took the course via the company intranet at his/her workstation. Most CSOs scheduled their learning for slow times so that down time was minimised.

Because eLearning occurred at the workstation, operational benefits resulted. eLearning time could be scheduled to suit individual needs. There was no need to provide coverage for a staff member away on a training course. Both scheduling and rescheduling of eLearning experiences was flexible and relatively easy.

The following indirect savings were not included in the ROI calculation above:

- Technology transfer: the client acquired expertise and processes to run eLearning programmes (and has since done so).
- A group of instructors has received eLearning and practice in the skills needed to function effectively as eCoaches for eLearning courses.
- A large number of the company's employees are now comfortable and competent in learning via the eLearning approach used (initially they had been quite negative) – more than two-thirds "liked learning this way" and more than three-quarters were "quite willing to receive future training using eLearning."
- The company can extend the new programme to additional CSOs without incurring additional expense except deployment costs.
- Although certain "soft benefits", such as CSOs' increased confidence in serving callers and in providing better answers to callers, are difficult to quantify and assign a dollar value to, it is likely that they will have a positive effect on the quality of service and job satisfaction.

2.8 The Bottom Line

Two critical business objectives of the company's eLearning initiative to multi-skill its CSOs were to maximise training dollars and to reduce training time. Both were achieved and the savings in eLearning costs and eLearning time were not made at the expense of quality or effectiveness.

3 Conclusion

The impact evaluation described in this paper is not intended to be promoted as the ideal impact evaluation. Instead, it is a realistic portrayal of a typical impact evaluation that can be conducted in a corporate context at a reasonable cost within a satisfactory timeframe. More extensive and more rigorous evaluations would certainly be possible, but they would also take more time and cost much more money. This evaluation was able to build a case for impact using multiple data sources as opposed to providing unassailable scientific data that the eLearning caused the observed results. We think that this will be viewed as a more viable approach in most corporate contexts.

Abstract: With the increasing availability of information on Internet information providers, like search engines, digital libraries and online databases, it becomes more important to have personalized systems that help users to find relevant information. One type of personalization that is growing in use is recommender systems. This paper presents Mylibrary, a web personalized digital library that provides personalized services and a recommender system (RecDoc) to support the user task of finding useful information. MyLibrary offers an environment where users can store read documents in a user profile, can rate and comment these stored documents, can visualize the documents percentage rate in a chart representation, and share information with other library users. With the information stored in the user profiles, MyLibrary offers a recommender systems, RecDoc, that indicates documents based in already read documents by the user (content-based) or based in the collaboration with other users (collaborative filtering).

Introduction

The progressive growth of online information available through information services on the Internet, like search engines, digital libraries and online databases, makes people feel information overloaded. These information services provide a search and a retrieval system to the web community, but they do not provide any personalized support to individual users, or poorly support them (Amato 1999). According to (Lawrence 2000), Web search engines generally treat search requests in isolation. The results for a given query are identical, independent of the user. Consequently, few results returned by a search engine may be relevant to a user (Mizzaro 1997). Next generation search engines will make increasing use of context information from users (Lawrence 2000). One example of this attempt is the Yahoo experience in designing personalized features, presented in (Manber et al. 2000).

Providing personalized information search and delivering services, is likely to be the first step to make relevant information available to people (Amato 1999). One type of personalization that is growing in use is recommender systems.

Recommender systems improve access to relevant products and information by making personalized suggestions based on previous examples of a user likes and dislikes, or use collaborative filtering methods that built their recommendations on other users' preferences (Mooney & Roy 2000). Recommender systems have been developed in response to an actual need: helping people deal with the world of information abundance and overload. They enable people to share their opinions and benefit from each other's experience (Terveen & Hill 2001).

Digital libraries, such as others information providers, should be able to assist readers by providing personalized services and automated recommendations (Mooney & Roy 2000). Guided by this premise, a personalized environment, named MyLibrary, was developed to the Software Engineering

Digital Library. The library stores the scientific production of the Software Engineering group at the Federal University of Rio de Janeiro. The library also collects references to documents produced by related research centers, and universities.

MyLibrary provides a personalized environment where users can store read documents in a user profile, rate and comment these stored documents, visualize the documents percentage rate in a chart representation, share information with other library users and take advantage of their experiences to select documents evaluated with better rates. With the information stored in the user profiles, MyLibrary offers a recommender system, RecDoc, that indicates documents based on the premise that the user would like to have access to similar documents defined in his profile (documents already read by him) or documents that have been rated by similar users (collaboration with other users).

This paper is organized as follows: a first section that shows the Software Engineering Digital Library with information about the collection and the library search system. Then, a second section describes MyLibrary, a personalized environment based on user profiles that offers a recommender system. Finally summary and work in progress are shown.

Software Engineering Digital Library

The Software Engineering (SE) Digital Library centralizes the scientific production of the Software Engineering group at the Federal University of Rio de Janeiro and stores references to documents produced by others related research centers, and universities. The participants of the research group are professors, researchers, and MSc. and PhD students. In this educational environment, a library is useful to maintain an updated bibliographical collection, and to provide courses' materials. Besides, the library is available online on the Internet, so the students can search the collection to support their research activities anytime and anywhere.

According to (Entlich et al. 1997), the most important characteristic of a digital library is its collection, whose main requirement is the selection of qualified materials. Thus, the SE group opted to maintain a manual control of documents selection and classification. They use a catalog system available at the library to register and classify documents. The library collection is composed of congress articles, journal articles, thesis, technical reports, books, and technical standards.

The SE digital library search system is based on specific fields of this type of application, such as title, author, and keyword. Besides, other search options was added to library search system to attend educational requirements of this research group, for example, search by course, by project, and by conference. All search options of the library is represented in (Figure 1). The main search interface showed in this figure is the search by keyword option where the user can combine a group of keywords or can select a keyword in the library keyword list.

BEST COPY AVAILABLE

According to actual needs, digital libraries, like others information providers, should offer personalized functionalities and delivery services. Guided by this premise, a personalized environment (MyLibrary) and a recommerder system was developed to the SE Digital Library. MyLibrary is described in the following section.

MyLibrary: a personalized environment to the SE digital library

Concerned to provide personalized services to the SE Digital Library, the first step toward personalization was the addition of a user profile to represent user information needs. The second step was the development of a recommender system that manipulates the user profiles to find relevant information. The resulting personalized environment, MyLibrary, is available only to registered users. The library search system is still available to any user that accesses the library, as ilustrated in (Fig. 2). This figure also shows MyLibrary architecture.

Figure 2 - MyLibrary architecture

The *Web user*, not registered at the library, has access to the environment called "open system". Through the open system, the user interacts with the library search system, querying documents by title, author, keyword, course, project, and conference.

The *DL registered user* has access to the personalized environment and the recommender system. There are two databases composing the library: Documents database that stores all documents; Profiles database with the user profiles representation.

MyLibrary embraces personalized services, such as keep document in the user profile, rate and comment these stored documents, and send a document to a friend by e-mail, as shown in (Fig. 3). This figure also represents the document description, average rate, a graphical representation of all rates for the document, and a list of comments made by the users.

BEST COPY AVAILABLE

With the documents evaluation, a average rate can be associated to documents and displayed in the list of documents returned by the library search system. A user can takes advantage of others users experience to choose better rated documents in this list. Besides, the users' comments are showed when the document is selected in list, as illustrated in (Fig. 3).

User profile

A user profile schema to digital libraries, proposed in (Amato 1999), was adapted to MyLibrary according to particularities of the SE Digital Library. The resulting profile schema is showed in (Tab. 1) below, and includes all information to be represented in the user profile.

Personal data category	• Name, e-mail, password and user occupation (student, professor, etc.)
Gathering data category	• A user keyword list that represents user interesting area. • Digital documents are available in PDF format. • The user only query the library database.
Delivering data category	• Delivery mode: the system sends an e-mail to the user suggesting new interesting documents. • Delivery time: the recommended items is available in the personalized environment when the user enters the system.
Actions data category	• Stored read documents. • Rated documents (from 1 to 5) • User relevance feedback (the users explicit rate documents and recommendations).

Table 1 - Mylibrary user profile schema

Initially, the profile is created when the user submits a registration form available at the library. This form contains information about personal data, academic data, and a list of keywords. While the user interacts with the library search system, stores documents in the user profile, submits rates and comments about them, the profile has been continually updated. The list of read documents and their evaluations are available at the user profile, as illustrated in (Fig. 4).

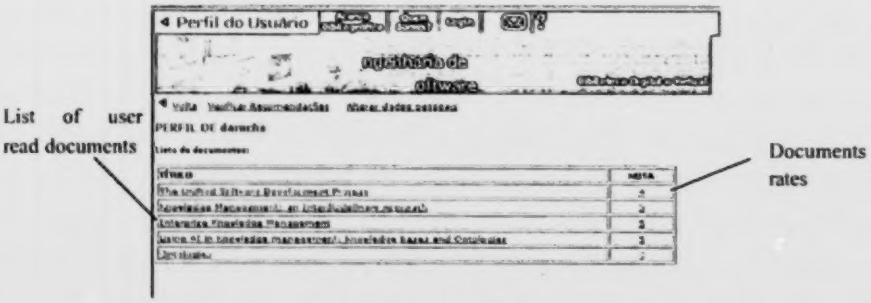

Figure 4 - User profile screen

With the information stored in the user profiles, a delivery service has been implemented through a recommender system named RecDoc. The system is described in the section below.

BEST COPY AVAILABLE

RecDoc: Document Recommender System

Having emerged in response to technological possibilities and human needs created by the WWW, recommender systems aim to mediate, support and automate everyday process of sharing recommendations (Terveen & Hill 2001). There are two main recommendation systems approaches (Balabanovic & Shoham 1997): content-based and collaborative filtering. In the content-based approach, the document recommendation is done through comparison of similar documents to those the user has already seen and rated . The collaborative approach explores techniques for matching people with similar interests and then making recommendations on this basis (Sarwar et al. 2001).

Content-based approach has its origins in the Information Retrieval research community and employs many of IR techniques and algorithms. Content-based recommenders believe in the intuition "find me things I have liked in the past". Documents are recommended based on the comparison between their content and user profiles (Balabanovic & Shoham 1997). Systems that use this approach are InfoFinder and NewsWœder (Lang 1997).

Recommendation systems adopt collaborative filtering based on the premise that people looking for information would like to know what other people already found and evaluated. Systems that use this approach are GroupLens (Resnick et al. 1994), Fab (Balabanovic & Shoham 1997) and Firefly .

RecDoc uses hybrid approach taking advantage of these two approaches: content-based and collaborative. The Fab system, developed by Stanford University, also uses the hybrid approach for recommendation of Web pages.

RecDoc provides to the user:

1. to receive, for each database update, new documents that are interesting to the user trough the comparison between the document keywords and the user profile (**content-based approach**).
2. to receive documents rated by similar users (**collaboration approach**).

RecDoc applied one K-nearest neighbor algorithm to perform the collaborative filtering recommendation. These algorithm is one of the most successful recommendation technique to date on the Web (Sarwar et al. 2001).

Every time that RecDoc indicates a document, the user is suggested to evaluate the recommendation, accomplishing what is called relevance feedback. Accurate profiles are so much important in the content approach (to guarantee appropriate recommendations) as in the collaboration approach (to guarantee that users with similar profiles are really similar).

Summary and Work in progress

This paper presented the SE Digital Library, available on the Internet. The library has been in use to support activities and courses of the software engineering research group at the Federal University of Rio de Janeiro.

Then, MyLibrary a personalized environment based on user profiles and a recommender system (RecDoc) was described. RecDoc is an implementation of a hybrid content-based/collaborative document recommender system. The recommendation of documents seems to be a useful service to deliver relevant information to the library users.

At this moment, a prototype of RecDoc has been evaluated trough a testbed database.

An Agent Architecture for Asynchronous Learning

Stephen Rochefort
Department of Electrical and Computer Engineering
University of Calgary
Calgary, AB T2N 1N4
rochefor@enel.ucalgary.ca

Abstract: Education delivery systems have evolved from content delivery mechanisms to collaborative environments. The next step in this evolution is to provide greater support for asynchronous learners, those that progress through course material with little or no support from the instructional team. The integration of web technologies with artificial intelligence techniques and multi-agent environments provides an architecture that supports the development of asynchronous-based systems. Autonomous agents are capable of providing ease of use and guidance through the introduction of natural language interfaces, knowledge processing, inferential reasoning and interactive wizards.

Introduction

Research and the application of distance education techniques has been the center of much attention in recent years. Numerous educational institutes are now providing some form of distance education curriculum. For example, Athabasca University in St. Albert, Alberta uses networking software to offer correspondence degrees. Memorial University in Newfoundland offers courses using audio-conferencing with computer linkups. Video-conferencing is also widely used since Queens's University in Kingston, Ontario, pioneered its use for a master of business administration program.

Distance education technologies have progressed from the user of paper materials to audio and video conferencing to Internet delivery, with many variations in between. The latest technology, the Internet, provides up-to-date materials retrievable instantly on-line from sources across the globe.

Advancements in the use of the Internet for distance education have focused on the publishing environment that the World Wide Web has become. Instructional teams are able to make course materials available on-line. More recent advancements have delved into supporting advanced pedagogies based on the principles of active learning, collaboration, multiplicity, and knowledge building (Harasim, 1995; Harasim, 1996). These educational systems facilitate course design, management, and evaluation, by providing software to enter and maintain, for instance, grade information or shared documents. They also provide virtual conferencing facilities, which allows for messages to be broadcast to virtual groups, which then can be organized by reply threads in order to follow up on a given discussion subject. Paramount behind these concepts is the idea of engaging learners in cooperative rather than competitive pursuit of knowledge.

Unfortunately, education delivery through the Internet stills falls short of the great possibilities that exist. There are two essential extensions that are required to harness the medium. First, current systems have little or no support for asynchronous learners who require support that enables them to find their own solutions and approaches to learning the course material. Second, communication in distance delivery systems still proceeds on an individual-to-computer basis with the learning software in charge of organizing the communications into coherent threads that the users can consult individually. Simultaneous interaction between various students and teachers is simulated and mediated, rather than facilitated, by the software.

This paper describes an architecture for Internet-based education delivery systems that provide asynchronous learner support and facilitated interactions. This architecture makes use of a distributed and mobile, multi-agent system, using artificial intelligence techniques. The architecture has been implemented and tested in the Logic Programming in Education for Asynchronous Learning Environments (LPed ALE) system.

LPed ALE

The Logic Programming in Education for Asynchronous Learning Environment (LPed ALE) system is a full distance education delivery tool (Rochefort & Dahl, 1999; Rochefort et al, 2000). It provides standard education delivery facilities such as content delivery, communication, and course management and evaluation. Beyond these basic features, LPed ALE provides tools that support asynchronous learning through real time communication, a natural language interface allowing the user to control the tools with natural language, concept based searching and indexing, and interactive software agents that work with the user in their activities in the system.

LPed ALE expands previous work on the LogiMOO virtual world for distributed group-work over the Internet (Rochefort et al, 1998). These systems integrate web technology, via the Java programming language, and artificial intelligence techniques, via the Jinni logic programming language (Tarau, 1999). The integration allows for greater support of natural language interfaces, knowledge processing and interactive student assistant wizards. The use of artificial intelligence techniques allows for the development of systems that provide a more interactive and supportive environment for asynchronous learners. Furthermore, these techniques allow knowledge about the interactions to be captured and used to guide the learner through their experiences within the system.

The natural language interface uses a controlled subset of English that is translated into commands that are executed in the environment (Rochefort et al, 1997). Natural language processing techniques such as anaphora, relatives and multi-sentential input through an original mechanism, Assumption Grammars (Dahl et al, 1996; Tarau et al, 1996), enable the system to keep contextual information about the user's interactions and customize responses and queries to the user.

Concept-based hierarchies are used to index source and, in turn, allow the user to query the system for information. When a user queries the system through the natural language interface, concepts of interest are extracted from the semantics of the text and then matched to concepts listed in the index hierarchies. Sources that match a user's interest and intent in the query are then presented. Concepts can further be generalized or specialized to assist in locating relevant information.

Interactive student wizards are provided through agent technologies. These mobile software robots provide asynchronous support by traveling to student computers to interact with the student, receiving queries and determining appropriate responses, and interacting with the student to solve their problem(s). The agents are capable of traveling to course machines in order to process knowledge bases and to locate information and answers to student queries.

Supporting Asynchronous Learners

The basic components of an educational environment include ease of communication, ease of presentation, and ability to expand. For a cooperative learning environment, these basic components are extended with multi-user capabilities and interactivity. For asynchronous learners, there must be support for guiding students through a learning path with little or no interaction from the instructional team.

The abilities to organize shared information intelligently and to provide guided and response system support are paramount for the feasibility of such objectives. Systems that do not possess any kind of inferential capability ultimately fail the task. Logic programming, or other automated deduction mechanisms, will come to be recognized as the necessary way to extend educational delivery systems.

LPed ALE provides the basic components of educational environments through the web-based facilities that support extensible material presentation. It also supports collaborative work, allowing students working on the same project to interact amongst themselves and the instructional team. Asynchronous support is offered in LPed ALE through a system of collaborating and mobile agents.

LPed ALE implements asynchronous support through various features. The natural language interaction hides the complexities involved in interacting with a large software system and it encourages conversation interactions which can later be extended to voice-based interactions. A frequently asked questions (FAQ) knowledge base allows students to ask and receive answers in an automated way. The student assistant agents is a mobile software robot that interact with students to lead them down a path of learning and uses mobility and collaborative techniques to assist the student. An instructional assistant agent is used to administer instructional goals, such as interactive examinations, to a group of students.

LPed ALE Architecture

The LPed ALE system is a web-based, collaborative multi-agent environment implemented in Jinni (Tarau, 1999), a lightweight, multi-threaded, logic programming language, intended to be used as a flexible scripting tool for gluing together knowledge processing components and Java objects in distributed applications. Jinni allows the web-based components and the artificial intelligence components to be isolated. The result is that static aspects of the system such as the user interface are created only once in Java while the dynamic aspects of the system such as the agents, which are implemented using artificial intelligence techniques, can be updated while the system is executing.

Multi-Agent Systems

Agent and Multi-Agent Systems (MAS) are a new software development paradigm where the principle idea is that software systems can be broken down into small, efficient, and autonomous software robots. These agents work on behalf of a user to solve more complex computing problems than those achieved by more conventional algorithmic programming. An inherent characteristic of MASs is the spatial and temporal distribution of processing knowledge.

Agent systems have advanced from the basic notions of beliefs, goals, plans, roles, and groups. The intent is that agents are "individuals" that have goals and responsibilities that are accomplished in an autonomous nature. In order to accomplish goals, agents make use of knowledge about themselves, other agents and the environment in which they exist in order to develop beliefs, plans, and roles.

Distance education delivery systems can benefit from multi-agents systems because of their inherent nature of distributed processing and knowledge. The use of agents creates a partnership with the learner and together the two can address learning issues encountered in asynchronous learning. In order to take full advantage of multi-agent systems, education delivery systems require an architecture that supports the various aspects of asynchronous learning.

Education Delivery System Architecture

The LPed ALE multi-agent system architecture (Figure 1) consists of three main components. A Java manager application executes on course servers to provide services to the instructional team including content delivery, student management, and agent configuration. On each student machine, a Java manager application provides a portal for the student to retrieve course materials, complete course assignments and interact with system agents. The third component consists of the mobile, collaborative agents that provide asynchronous learner support.

LPed ALE Manager Applications

The *Site Manager* is a Jinni process managing a blackboard of information related to all course sites and student sites that exist. In either case, when a course site becomes active to offer its contents or when a student comes on-line, these two types of sites must register with the Site Manager. This effectively makes the Site Manager a global "phone book" of all course sites and student sites currently active. Once a site has registered with the Site Manager, it can participate in all networked activities. This includes information access, mobile agent interactions, and chat.

The Site Manager must be located on a computer that makes accessing optimal. This could be a remote machine unrelated to a specific course site or student site but typically it would be the main site where an institution would set up its courses.

The *Student Manager* is a Java process responsible for providing access to core activities that a student would require to use the system. This process is located on a networked computer set up to interact with web-based delivery sites. A Student Database is kept on the same site to store all information collected during student activities (student notes, communications, agent interaction results) as well as maintaining a student profile. A student profile contains information specific to the student including login parameters, course enrollment identification, along with data on student activities.

The Student Manager provides a controlled natural language interface through a web-browser. This interface allows students to interact with the system using a natural language such as English. A natural language interface enhances the point and click nature of the interface. This provides students with the opportunity to interact and directly manipulate the environment.

The activities that can be performed through the Student Manager include:

- Course registration/deregistration/login/logout.
- Course participation (accessing and participating in course activities).
- Support agent access.
- Chat.

Figure 1: LPed ALE Multi-Agent System Architecture

The *Course Manager* is a Java process responsible for providing access to the core activities that an instructional team would be involved in to set up and administer a course site. This process is located on a networked computer set up to deliver web-based material. A Course Database is kept on the same site to store all information about the course(s) (lecture notes, demos, frequently asked questions, instructional team profiles, and any links to information resources) as well as maintain information related to course statistics, and student grades and profile information.

Each course on the course site is given a course profile which provides links to the different components of the course information set. This profile is also used to store statistical information such as timestamps indicating the last update and page access information.

BEST COPY AVAILABLE

The Course Manager includes a controlled natural language interface that allows the instructional team to interact with the support agents (FAQ, search, etc.) just as a student would. This is useful for testing facilities from a student's point of view.

The activities that can be performed through the Course Manager include:

- Course creation and management.
- Course enrollment.
- Grade management.
- New course material indexing.
- Frequently Asked Questions knowledge base update.
- Support agent access.
- Chat.

LPed ALE Agents

As described in earlier, agents are modules of software, situated within a computing system, that are knowledgeable of the environment and their responsibilities within that environment, and are capable of autonomous actions to accomplish goals. Within LPed ALE there are numerous agents, implemented in Jinni, interacting with the external entities, databases, and managers. The agents have a key role in providing assistive support to all external entities (i.e. the instructional team and students).

The *Natural Language Interface (NLI) Agent* is responsible for tokenizing and parsing controlled natural language input, in the form of English statements, into system commands and then invoking those commands. This agent exists in both the course application alongside the Course Manager and in the student application alongside the Student Manager.

The NLI Agent communicates with the respective manager, which maintains a kernel of commands, to invoke system commands. These invocations can then lead to information being retrieved and displayed or agents being activated or deactivated.

The *Chat Agent* is responsible for processing incoming and outgoing chat messages. Incoming messages received from other Chat Agents are placed on the *Message Board* until they are processed. When they are processed, the Chat Agent presents the incoming messages to the user through the web browser interface. These messages are formatted to show the sender of the message.

Outgoing messages from the User are stored on the Message Board until they are processed. At processing, the Chat Agent looks up the recipient of the message through the Site Manager and then the message is passed to the respective Chat Agent at the recipient's site.

The *Message Board* is a process managing a local blackboard of chat messages. This blackboard stores the messages being sent from and sent to the local user. These messages are managed by the Chat Agent. All messages are stored with sender and receiver information to make identification easy.
The *Frequently Asked Questions (FAQ) Agent* is a mobile agent that processes queries on a FAQ knowledge base. A user activates the FAQ agent through the respective manager's NLI Agent by asking a question in a controlled form of English. The NLI Agent will parse the question and log it with the FAQ Agent through a system command in the respective manager.

When a FAQ Agent receives a query, it parses the query and then searches for related questions in the FAQ knowledge base. When a match is found, corresponding answers are retrieved and returned to the respective manager which then displays the results.

The FAQ knowledge base stores representations of questions in categories based on their relevant topic. The relevant topic is the key to making a match between the user's question and the question-answer pairs stored in the knowledge base. The result returned to a user will be all question-answer pairs that correspond to the topic of the user's question.

The *Search Agent* is a mobile agent that receives queries via the NLI Agent and the respective manager. When a query is logged with the Search Agent, the agent will return to the Course Manager to compare the search parameters with the categorization of course documents stored in the course database. The resulting matches will be returned to the respective manager to present the user with a list of links that correspond to related documents. These links are presented in the web browser portion of the user interface thus allowing the user to click on the link and load the respective document.

The *Index Query Agent* is a mobile agent that is used to provide concept hierarchy information to requesting users. The Course Database contains a concept hierarchy related to the specific course. This hierarchy ranges upwards in a computing science tree fashion with generalized concepts while ranging downwards with specialized concepts.

Users can make controlled English requests for a generalization or specialization of a specific topic. In the case of generalization the Index Query Agent returns the parent of the specified topic. In the case of specialization the Index Query Agent returns a list of child concepts.

The *Tutor Agent* is a mobile agent responsible for interacting with a user through a question-answer paradigm. The user is able to make queries of the Tutor Agent via the NLI agent and the respective manager. When the Tutor Agent receives a question, it parses it and determines a course of action and where possible solutions may exist. The agent then moves to and interacts with the Course Manager and other agents to resolve the requests. The interaction between user and Tutor Agent continues until the user asks the Tutor Agent to deactivate.

The Tutor Agent acts as a facilitator of the other agents. Dependent on the query, the Tutor Agent may communicate with one or more of the other support agents in order to provide answers and further interaction.

The *Quiz Agent* is a mobile agent responsible for delivering quizzes to students. The quizzes are configured by the instructional team. A set of questions can be entered by the instructional team. Then the team constructs a test by assigning a set of questions to a test. Finally, the team can identify which students are to take which test.

Once the quiz agent has been configured, it waits for specified students to log in. When a student logs in and they are required to take a quiz, the Quiz Agent activates and starts a quiz.

When a student is taking a quiz the agent receives answers from the student and compares their answer to the correct answer. If the answers match, the agent continues with the next question or ends if there are no more questions. If the answers do not match, the quiz agent communicates the topic of the question to the Tutor Agent that then activates and starts an interaction with the student. When the student is done interacting with the Tutor Agent, and hopefully has a better understanding of the particular topic, the Quiz Agent resumes with the next question.

Status of the LPed ALE System

The LPed ALE system is a fully operational system with an implementation of the aforementioned architecture and agents integrated into the core distance delivery system. The system has been tested on a small subset of students from an Introduction to Computer Science class. Preliminary results indicate that students have a preference to the LPed ALE system over static delivery systems because some of their basic knowledge discovery questions and concerns could be handled by the system using the natural language interface and the supporting agent infrastructure. The results also indicate a need for a more elaborate support mechanism including handling exploratory questions in topical areas related to the core course materials, providing flexibility in the exploration scenarios, and providing a more robust set of semantics in the natural language interface.

Conclusions

The LPed ALE system is an implementation of a multi-agent system architecture. With the advent of autonomous agents, educational delivery systems will see a greater support for asynchronous learners. These agents will interact with and guide students as they progress through the learning process. They will act as surrogates for the instructional team providing answers, advice, and direction.

The future of systems such as LPed ALE will involve the exploration of agent usability. If a platform can be provided that enables end-users, such as the instructional team, to program the agents without the need for highly specialized training we could expect a fundamental change in the use of the educational delivery systems. If we consider the potential of a large population of instructional members and institutes capable of programming agents in these systems, we can expect a significant increase in the quality and the use of such systems..

It is through the development of easy to use multi-agent systems that educational environments can be expanded to support the natural learning behaviors of distance students. The use of artificial intelligence techniques is key to extended educational systems because of the intrinsic knowledge processing nature. Since course delivery is the passing of large amounts of knowledge it only makes sense to use tools that can manipulate the knowledge effectively.

Why web pages annotation tools are not killer applications? A new approach to an old problem.

Abstract

The annotation of web pages, and the possibility to share the notes with others, seems to be a powerful tool for an e-learning environment. Although several tools already provide such possibility, they are not widely popular, as one would expect them to be. We try to explain this fact, and propose a novel architectural approach that is, in our view, particularly suited to e-learning. We also present a tool that implements the proposed architecture.

Introduction

The idea of annotating Web pages is not a new one: early proposals date back to 1994, i.e. more or less to the pioneer-age of the WWW. Such functionality is appealing because it stresses the interactive character of the Web (that is most cases is instead sadly becoming more and more like a TV, where the highest level of "interaction" is to zap to another channel). Many uses can be supported by this functionality, so it is rather surprising that the idea did not have a large degree of success.

In particular, a tool providing the ability to add notes to a web page, and to share the note with other users seems to be particularly well suited to an e-learning environment. In fact, e-learning platforms aim not only at providing content to the student: in order to be effective they must support the learning process. For this reason virtually every e-learning suite provides at least some tool for asynchronous collaboration, like bulletin boards etc. Very often however these tool offer a poor degree of integration with the content of the e-courses. In many cases discussion among the "actors" (students and teachers) is carried on a forum: the forum though is a different tool, so it is separated from the presentation material. While sometimes this is perfectly acceptable, in many cases it is rather inconvenient since the discussion happens out of context, and many external references are necessary, making the whole process rather cumbersome.

Annotations on a Web page could in many cases be used instead of forums. A forum is certainly very well suited for the discussions of broad topics (as the metaphor implicit in the name implies). In many cases however the emphasis is on clarifying a point in a lecture. For instance, in the context of a programming course students are likely to discussing the code presented in an electronic lecture: in those circumstances, continuous references to "line X of code Y on page Z" make the writing and reading of the notes an exhausting task. Some discussions might even start using notes, and then move to forums. In other cases a discussion on a forum might be supported by notes included on a web page: we therefore see an interesting potential in using annotations.

Other uses might include assignments to the students that are published though a web site: in such a case the teacher could grade the assignment adding notes to it.

Yet another use could be a collaborative work made by students who cooperate producing a report: notes could be used in the same way, as revisions are possible using tools like MS Word.

Given the richness of scenarios that could be supported by web annotation, it is really puzzling that the tools publicly available on the web do not encounter more favor. In fact, since the early web years, sever projects have produced various tools for annotating pages. A list of them can be found on the "Collaboration, Knowledge Representation and Automatability" page of the W3C [COL], and a comparison among several such tools is available in [GAR].

We believe that lack of a wide success can be probably traced to a few different factors. On the one hand, too much a broad scope for an idea can be counterproductive: it is often better to address specific needs in a precise way rather than offering general support for a rather vague functionality. Most tools try to solve the problem of "annotating whatever page you want, wherever it is", and, to our knowledge, do not try to address a specific domain.

BEST COPY AVAILABLE

Another factor might be the absence of a ripe technology, that forces to use hacks ending up with a rather clumsy product. Early efforts were certainly penalized by the absence of a suitable technology. The resulting (annotated) pages were rather heavy, for instance using frames for showing the notes, or di add the annotations as footnotes, making the reading of the page sub-optimal.
Recent attempts (e.g. [KOI]) try to leverage the newest technologies, like the Resource Description Framework (the RDF specifications [RDF] provide a lightweight ontology system to support the exchange of knowledge on the Web), and use the notion of Xlink [XLI] and Xpointer [XPO]. Such a road, although very interesting and probably correct on the long run, makes however the deployment of the tool now (and in the next few years) almost impossible: the only browser that supports such choices today is, to our knowledge, the experimental browser of W3C: Amaya [AMA].
In the light of these considerations, we revisit the idea of web pages annotation. We restrict the focus to the domain of e-learning; we examine the existing software architectures supporting the annotations, and propose a different architectural approach. We also examine the technology that is available *now* in a *standard* way to obtain a user interface that is suitable for our application domain. We also set as a requirement the possibility of integrating our proposed approach in (virtually all) e-learning platforms. Finally, as a proof of concept, we implement a portable tool that allows introducing annotations in existing e-learning systems.

Software architecture: possible alternatives

The annotation tools that are available today are based essentially on two alternative architectures. The first possibility is to modify the behavior of the browser, so after fetching a regular URL and rendering the related document, it allows writing notes that can be stored locally, or on a separated web server. Similarly, for every page it can enquiry the (local or remote) notes repository, and visualize existing notes with the document. The approach is certainly interesting, since it completely de-couples the original material from the notes. The choice of having the notes stored locally is limited, since it doe not allow to interact with other people. The main limit of this approach is that modifying a browser is not a trivial task: the best solution could be one based on the notion of plug-in. However this would require maintaining different plug-ins for different browsers, and even for different implementations of the same browser (e.g. Windows vs. Mac vs. Linux, or version 5 vs. version 6).
The second major architecture is based on the concept of an "Annotation-server". The idea is to have an intermediate web server (proxy) that gets the requests, forwards them to the page server, gets the response and decorates it with the notes. Similarly, the proxy accepts the new notes and stores them. This architecture has some major advantages: it does not need a customized browser, and still preserves the separation between notes and content. However, the requested URL must be coded in a special way: "http://url_of_the_proxy?//http://url_of_the_resource": "real" URL is passed as a parameter to the proxy server. This can be an advantage (the same URL can be annotated through several proxies unaware of each other) but is also rather annoying, since every URL has to be "preprocessed" by the user in order to obtain the desired behavior. Moreover, following a link from a page does not pass through the annotation proxy, unless the proxy itself does not take the rather heavy burden of parsing all pages it delivers in order to suitably change all referenced URLs.
A third approach (not found in literature) could be possible: the Annotation-server could be registered by the user as the standard proxy used by the browser. In such way all requests pass through the Annotation server, and the problem of explicitly coding the URL would be completely solved. This solution is simple and brilliant, but it collides with the typical notion of a Proxy (a *local* machine, typically used for optimizing the network traffic, and often employed also for by-passing a local firewall).
By examining these architectures, one finds that the common denominator is the separation between the content server and the annotation server. This choice has obvious advantages:

a) the content server needs not to be aware of the existence of the annotation server;
b) one can define multiple annotation servers, supplying notes to (possibly closed) groups
c) it is possible to annotate just about every resource available on the web.

However, the limited success of the existing system witnesses that the balance problems overcome the advantages: some companies that offered an annotations as a commercial service discontinued their offering [THI].
We therefore think that it is worth revising the fundamental choices. In particular, we try to drop the nice but ambitious idea to be able to annotate any possible page. We focus on an e-learning platform that typically gets the (main) content from a limited number of servers (very often just one): our goal becomes therefore to be able to annotate only the pages of these servers. At this point, even the separation between annotation server and content server becomes less relevant, and we can concentrate

the whole job on the same server. This approach does not require a customized browser neither needs to pass through an intermediate server, relieving both problems encountered above. The last problem to be solved is to make the look and feel of the pages appealing, and to integrate the two functions (providing content and notes) in the same server.

The solution we suggest is to add the annotation functionality to a web server as Java servlets [SER]. Servlets are platform independent, and are supported by virtually every Web Server available on the market. The servlet gets the request for a page, locally searches a database that stores the notes, and builds an annotated page that is served back to the user. Similarly, another servlet gets new notes and stored them in the database. The original page is almost unchanged: we only require that:

a) It is written in valid XHTML (an HTML extension that is XML compliant)
b) The page contains a definition of the contexts to which notes can be appended.

The transformation from normal (even incorrect!) HTML to XHTML can be easily done by a free tool (Dave Raggett's HTML TIDY [TYD]). The definition of the contexts can be done automatically, with the chosen granularity: for instance each phrase, or each paragraph could be a context).

The notes are rendered in place using the standard subset of JavaScript that is commonly recognized by the most diffused recent browsers (Netscape Navigator and Internet Explorer versions 4 and above, Opera, Mozilla).

In summary, the architecture we provide contemplates:

a) an (automatic) conversion of HTML pages to a suitable (still HTML!) format
b) the filtering of each request though a system based on servlets
c) the storage of the notes on a database residing on the server that provides content.
d) The rendering of the notes in various way based on JavaScript.

In addition, we introduce the notion of users and groups so that the visibility of the notes can be restricted to particular actors (a class, the teachers, on particular person etc.). Such addition reflects the spirit of supporting or particular domain of election, i.e. e-learning.

Implementation: WebNotes

To proof the concept, we implemented a tool called WebNotes according to the architecture we suggest.

A first art of WebNotes is an automatic tool that performs the preprocessing of the page. During the conversion process the granularity of the markable context that can be annotated is chosen: it can be each word, each phrase or each paragraph. As we mentioned the process is necessary in order to guarantee that the resulting pages are XHTML compliant, and that the contexts are suitably defined. The resulting page is still normal HTML, although it conforms the more restrictive rules that make it XML compliant.

The pages requested by the user are filtered through a servlet enabled Web server, which maintains a set of notes and their properties (like ownership, visibility etc). Notes are shown in the text as tiny icons embedded in the page. Public notes are visible to everybody. After the user identifies him/herself through a login process, s/he can see all notes allowed by her/his privileges.

The user can toggle between two modes: browsing and editing. While browsing, when s/he moves the mouse pointer over an icon that shows the presence of a note, the note pops up on place. When moving the mouse away the note disappears, unless it was stuck by the reader, in which case it disappears only when explicitly closed.

In order to edit the page (adding or modifying a note) the user enables editing mode and simply clicks on the location where s/he wants to add the note. A popup window appears, and the users can edit/modify the note. In the basic version the note contains only text, without any formatting. In an enhanced version of WebNotes, the window contains an applet that allows writing HTML in a simple "What-You-See-Is-What-You-Get" fashion. We kept the applet separated in order to minimize the requirements we make on the browser, and in order to avoid delays related to its downloading.

The system is currently in the final stages of development, and already underwent some extensive testing with different browsers.

Although WebNotes can be used in various contexts, it was explicitly designed for deployment in an e-learning environment. We envision its use for performing some of the discussions that presently happen on electronic forums.

At the moment of writing, we plan to use its preliminary version on the field in some e-courses at the University of Trento during the last bimester. By the time of the conference we expect to have gathered statistics on its use and feedback by the users.

Since WebNotes is made by a series of Java Servlets, it can be deployed on any Servlet-enhanced Web Server (nowadays virtually every serious Web Server can has a servlet-compliant engine). We do not assume any special requirement on the client side, the only request being the support of (the standard subset of) JavaScript (that is available on all recent browsers). We tested our annotated pages with all the major players (i.e. Opera, Mozilla, Netscape, Internet Explorer) on several platforms without encountering problems. The notes are simple text, so their writing and the editing is performed in a normal web page. Also the administration of the system (e.g. group creation and maintenance) occurs in a web page. An enriched version of our tool also includes a Java Applet that is a HTML composer: this allows formatting the notes in a reach way, using the full power of HTML. Since the Applet adds functionality but is not needed to make the system usable, WebNotes can be configured according to the preference of the deployer. Thanks to these choices WebNotes can be integrated in most e-learning platforms, enriching them with a new functionality.

Related Work

As we mentioned at the beginning, although much emphasis has been given to the support of collaboration via web since the early WWW years [COL], a convincing technology has not yet emerged. Interesting approaches run from an almost uncontrolled interactive editing of web pages (wiki's [CUN]) to more controlled annotations. In particular, adding notes to a Web page is not a new idea *per se*. Tools comparable to what we present have been proposed in the past, but in most cases their architecture was dissimilar from the one we've chosen. The main architectural choices were either based on browser-specific tools, or on external mediator servers. A comparison of some available tools can be found in [GAR].

Brower specific tools (e.g. [COM]) require the use of a customized browser, which is certainly an inconvenient choice.

In the proxy-based approach, the annotation process is taken care of by an intermediate server, that collects the notes, gets the original page and present to the user a page decorated it with the annotations. This allows taking control of the annotation process, and in some cases is offered by commercial enterprises [ANN] [THI]. A non-commercial instance of this class of tools is CritLink [CRI].

Our tool is rather based on an automatic pre-processing of an HTML page to include the fields that (with the chosen granularity) define the markable locations, and rely then on a basic browser and on a standard web-server architecture to deliver the content. This promises to be a winning point, since it allows an easier integration with existing e-learning platforms.

A Conceptual Framework for the Development of WBT-Guidelines

Oliver Bohl, Dr. Jörg Schellhase, Prof. Dr. Udo Winand
Department of Business Informatics
University of Kassel
Germany
{bohl,schellhase,winand}@wirtschaft.uni-kassel.de

Abstract: Guidelines represent an important instrument in the development of Web-based Trainings (WBTs). They help to create reliable, portable, and interoperable, standardized WBTs of high-quality. The development of guidelines can be considered as a key success factor regarding the effectiveness of WBTs. The effects of Guidelines can be both, favourable and restrictive. Guidelines that are too rigid and strict could have counter productive effects. Therefore an optimum at guidelines is to be aimed at, taking notice especially of producers and learners. This article discusses potentialities and restrictions of WBT Guidelines, supplies a description framework for WBTs and illustrates its realization on the basis of a case example. It can thus be of assistance in the project-specific development of guidelines.

Introduction

The education network WINFOLine is an inter-universitarian online education network. It concentrates on internet-based training in the field of business informatics through high-quality online courses. The universities of Göttingen, Kassel, Leipzig, and Saarbücken form the core team. The network has various partnerships with universities and companies. On the basis of a pool of online-courses the network can supply customized online-courses for universities, suppliers of further training courses as well as for companies. From winter term 2002/2003 onward the network will offer an accredited master program. The Educational Network WINFOLine increases the choice for other suppliers of web-based trainings. The wider range of content, even of previously inaccessible content, can also create immediate benefit for students, university graduates or employees. The basis is a network that enables profits for its partners. Through the cooperation every partner shares specific professional competence. The student profits by the competences of renowned partners (best-of-peer). The Education Network WINFOLine focuses on a vast number of clients:

- *Educational institutions* with the focus on business informatics: as completion or enlargement.
- Other *educational institutions*: as a completion of already existing trainings as well as for the creation of new courses of study.
- *Graduates*, who are interested in further training in the field of business informatics. The offer can consist in a single WBT or in a complete course of study. In addition the network offers a Master Degree Program for Information Systems. This course of study aims at working people and graduates.
- *Corporations* can obtain contents from the network for the creation of their own special trainings in the field of business informatics. The contents can be used for single training or within a Corporate University.

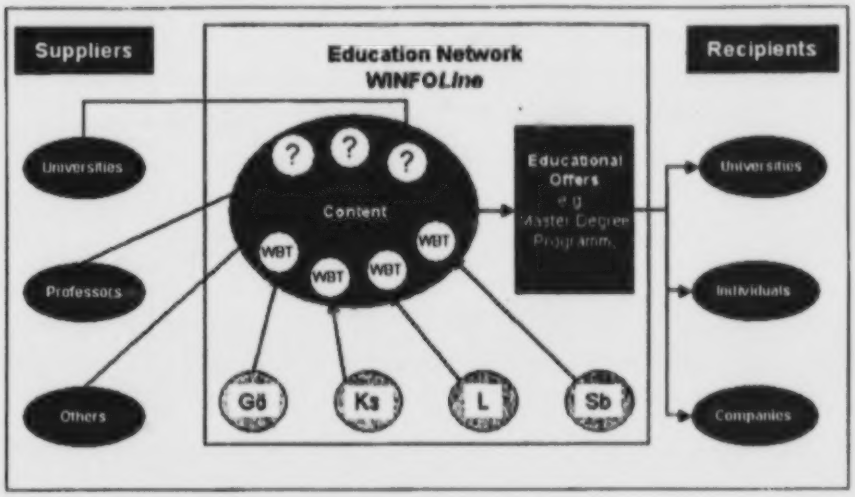

Figure 1: Structure of the Education Network WINFOLine

In order to guarantee a high quality of the online-courses it was necessary to develop a quality insurance concept on the basis of well defined guidelines for the courses of the education network WINFOLine. Two guideline catalogues have been developed for the production of WBTs. One of the catalogues contains guidelines referring to the production of online-courses within the network (produced by the core team of the network). These courses meet the high demands regarding the uniformity as well as the technical and didactical quality of the online-courses. The second catalogue defines a minimum standard concerning the technical and didactical quality of online-courses produced by external partners. Both catalogues distinguish between recommendations and compulsory guidelines.

The development of guidelines for WBTs serves to guarantee a high quality and reliability. The effective application of this control instrument can have crucial influence on the achievement of standards. The definition of guidelines is closely connected to quality assurance functions, media-didactical concepts, tutoring concepts, and the evaluation of successes in learning. Regarding these functions, guidelines can be considered as an instrument which should not be underestimated.

Different types of guidelines do not always have an obligational character. In most cases guidelines are published by institutions in order to establish or prescribe certain ways of behaviour within a small scope of discretion. In case these rules are neglected there can be sanctions. Generally, guidelines are systematically developed decision making aids with regard to appropriate methodologies in specific situations and there is still a certain scope of discretion, which allows to deviate from the rules in specific situations. However, they draw attention to noteworthy circumstances and serve users in forming a judgement. The term guideline used in this article covers the meanings of direction, instruction as well as recommendation, so the respective binding character of the guidelines has to be indicated explicitly. The approaches for developing guidelines, presented in this article, focus on producers and providers of Web based trainings (WBTs) in producer/provider networks.

Potentials and Restrictions of WBT Guidelines

Guidelines support the creation of uniform and high-quality WBTs. Even if a provider/producer network agrees on the application of a certain authoring tool, the definition of guidelines is necessary. Many guidelines, which serve the ensuring of a certain minimum quality, can not or not exclusively be guaranteed by only one authoring tool. WBTs, which are produced with the same authoring tool, often indicate a common basic characteristic. This does not mean, however, that WBTs, which are produced with the same authoring tool are uniformly structured. Flexible authoring tools permit a large and creative scope.

BEST COPY AVAILABLE

Guidelines aiming at a uniform Look & Feel of WBTs, require a consent of the WBT authors. It is important that all partners adhere to this consent in order to achieve a standard. On the one hand one should consider that the appointment of certain guidelines is necessary in order to obtain a uniformity regarding functionality and optics, as well as a desired quality level. On the other hand strict and too closely seized guidelines can lead to unwanted side-effects. In the process of defining guidelines different aims have to be considered carefully.

Learners, customers (e.g. enterprises or education brokers), and creators of WBTs benefit from the definition of guidelines. From the learner's point of view a higher quality of the WBTs, an increased attractiveness of learning, a uniform appearance, a uniform structure of the WBTs, uniform functionalities within the WBTs, uniform services and simplified management avoid a cognitive overhead. The customers can take full advantage of a higher quality of the WBTs, an increased motivation on the side of the learner, a uniform appearance (Corporate Identity), the uniform structure of the WBTs, and of an increased acceptance on the part of the user. Content developers benefit from a higher quality of the WBTs, a Corporate Identity, an increase of the everyday suitability and acceptance on the part of customers and learners, more economic development, maintenance, administration of the WBTs as well as of he simplicity to handle tutoring.

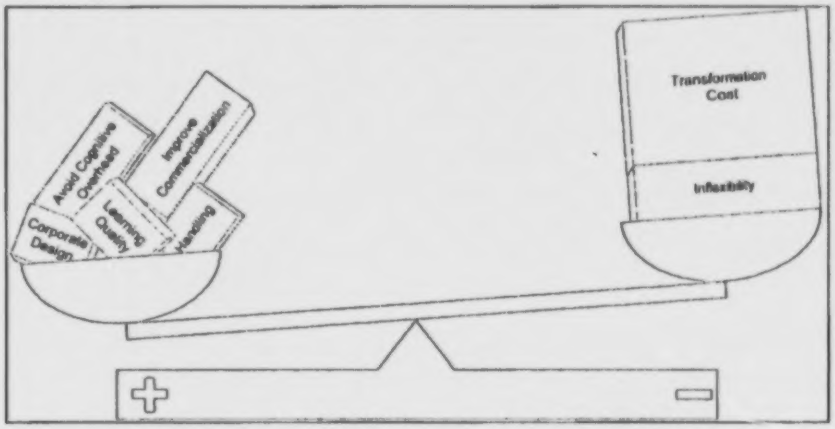

Figure 2: Advantages and Disadvantages of Guidelines

However, disadvantages or restrictions can result from too rigid guidelines. The realization of guidelines is very often problematic. Depending on production process or assigned tools certain guidelines are realizable only at very high expenditure or not realizable at all. Guidelines can form a barrier for any partner. The revision or adjustment of already existing WBTs could cause very high expenditures or not be feasible at all, since e.g. a tool is used, with which certain guidelines can not be fulfilled. The entrance barrier is even higher when already existing WBTs of other producers have to be integrated into the product portfolio of the network. A further consequence could be the incompatibility with the products of prospective customers. These could require for their part the adherence to certain guidelines, then WBTs would have to be adapted to the Corporate Design of the customer. This special adjustment of WBTs usually has high transformation costs as a consequence. Last but not least, the increased inflexibility regarding modifications in the design of WBTs, functionality extensions and technical advancement has to be considered. Because an innovation process in the production of WBTs is necessary, modifications of the guidelines must be implemented within a provider/producer network. This becomes the more difficult, when the network is large and when the production processes are varied. Modifications of the guidelines can lead to the problem that all WBTs have to be redesigned and can thus involve high expenditures. Therefore, too rigid guidelines could impede innovations in the production of WBTs.

If one regards these pros and cons, it becomes obvious that an optimum at guidelines is to be aimed at, in order to realize the advantages and avoid the disadvantages. On the one hand guidelines should guarantee the highest possible quality as well as a minimum of uniformity. On the other hand guidelines

BEST COPY AVAILABLE

should not have an effect that is too restrictive. The readiness of prospect providers to participate in a provider/producer network is influenced negatively by high costs of adjustment of available materials to defined guidelines. In addition guidelines should guarantee some room for prospective providers to realize their own ideas (e.g. the creation of multimedia contents). Too rigid and strict guidelines promote neither the quality of learning contents, nor do they meet the principle of the freedom of teaching. The freedom of editing WBTs should therefore not be limited unnecessarily.

A Framework for WBTs

The framework presented in this passage can be used as a basis for the definition of guidelines. It contains the following categories: construction of WBTs, production of multimedia content, design and layout, interchange of data between the WBTs and the learning management system and technique. The framework contains background information and examples.

Construction of WBTs

Guidelines of this category define the structuring of contents, the navigation concept, access structures, functionalities, support of different learning styles, orientation hints, tests, and communication services of WBTs.

- *Structuring of Contents.* Learners are used to hierarchical structures and linear sequences, hierarchies and sequences can serve a lot to structure the contents of WBTs. (Schellhase, 2001)
- *Navigation.* There should be a concept for the navigation in WBTs. Navigation aids can support the learner. In order to support the navigation process web-browsers include special functionalities such as e.g. backtracking, indication of already followed hyperlinks, history-lists, and bookmarks. WBTs can offer additional support in navigation for the acquiring of contents, examples are the possibility for achieving a quick overview (e.g. through an optional hierarchical or non-hierarchical structure, like a table of contents or site-maps), the indication of already read material (already acquired content could be marked in the table of contents or in the site-map), different types of links maybe with support by the use of visual signs and an obvious classification between the different types and different search-features like meta-information and keywords. (Moser, 1998, p.43)
- *Access Structures.* Appropriate access structures support search activities of the learners. Internal and external referential hyperlinks could be shown in a separate list. A list of figures and videos enables the learner to get direct access to any figure or video. Furthermore a list of references allows direct access to all parts of the WBT where a reference has been used.
- *Functionalities.* WBTs could provide several functionalities like e.g. full text search mechanisms, plugin-testers, administration of bookmarks, learning-account, direct addressing of content, keyboard control, glossary as well as direct access to self learning exercises. While creating new WBTs the focus has to be on aspects about the usability and the reliability.
- *Support of Different Learning Styles.* WBTs could offer configuration options that leave the choice to the learner in which way he would like to use the WBT (e.g. acoustic and/or visual). One can imagine many more configuration options and possibilities for creating a WBT that could support different learning types, learning phases, and learning situations.
- *Orientation Hints.* Orientation problems are a typical problem using hypertexts. (Schaumburg, 1996, p.109) remark that in particular beginners do not know how to handle the explorative freedom of hypertexts. Orientation problems can effect the learning process negatively and should therefore not be underestimated. (Schaumburg, 1996, p.110) The avoidance of orientation problems by means of a high quality hypertext-design represents an important point in the creation of WBTs. (Lynch, 1999, p. 43f.) For that reason WBTs should contain several options that support the orientation within the WBT. The offering of a list of milestones could be helpful.
- *Tests and Exercises.* WBTs which are used for further training require special tutoring options and services. Tutoring includes the supply with exercises that can be solved by the learner during the learning process. (Sasse, 1998) show a detailed catalogue of requirements with regard to web-

based systems for the support of tutoring and supply of exercise material. The following types of exercises could be used: multiple-choice-questions, crossword-puzzles, gap texts, open questions with sample solutions, drag and drop exercises, matching exercises, general interactive/multimedia exercises, and case studies. Types of exercises can be classified into self learning exercises and tutored exercises. (Moser, 1998, p.46) The access to the exercises can be offered through lists of exercises and within the learning content. The exercise results could be shown in a personal learning account. Furthermore the WBT should be able to interchange data with legacy systems via defined interfaces.

- *Communication Services.* Various synchronic and asynchronic communication elements can be used for the support of the learning process. Typical elements are e-mail (possibly context-related), web-based forums, and chats. Sometimes WBTs provide more complex communication elements, like e.g. video conferencing.

Production of Multimedia Content

The production of multimedia contents depends a lot on the contents of the WBTs. For example a WBT on modelling could contain animations which show each single step in the modelling process. This animation can be accompanied by short texts in written or spoken form. Other WBTs could use short videos to support certain parts of the lecture. There is a lot of room for the creation of additional learning materials. It should not be restricted by standardisation efforts.

Design and Layout

The design and layout of WBTs has great influences on the acceptance and attractiveness of WBTs. The layout should meet variety as well as constancy.

Data Interchange with the Learning Management System

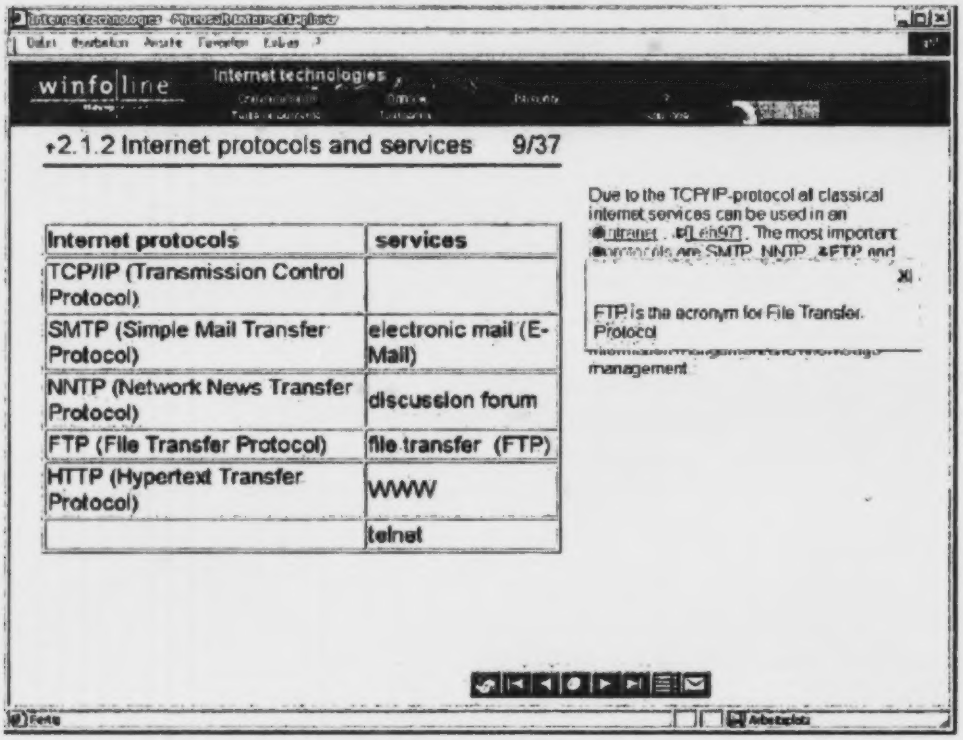
The access to WBTs is often offered via learning management systems (LMS). The communication between the WBT and the learning management system should be based on established standards. An optimum data interchange between LMS and WBT is an essential basic requirement for lots of WBT-related services of the LMS. AICC and SCORM are standards that are appropriate for data interchange between the WBT and the LMS. The SCORM-standard is based on both the AICC-standard and the IMS-standard. (Cohen, 2002) One essential advantage of these two standards is the portability of contents between different LMS and the independency on the chosen learning management system. The expenditures for the adaptation of the WBTs to a certain learning management system fall. WBTs conforming to the standards offer essential advantages: they can be used on any learning management system conforming AICC/SCORM-standard, they offer authentification mechanisms and are able to interchange certain data like general user data, meta data on any learning unit as well as a multiplicity at interaction data, e.g. path choice, current position in the WBT, comments, retention times, and test results in a standardized way.

Technical Aspects

Requirements concerning hardware and software should be specified. This includes the system requirements (browsers, operating systems, and plugins). Multimedia elements that require a high bandwidth should be provided through a CD-ROM/ DVD. Complete WBTs could be offered online and offline. In this way communication costs on the side of the learner can be reduced.

Case Study: Guidelines of the Education Network WINFOLine

The above described framework served as a basis for the definition of project-specific WBT-guidelines. Many guidelines base on lists of criteria concerning the WBT-/CBT-design or on experience evaluation results gained during the project. The guideline catalogue contains 160 items on the construction of WBTs, the production of multimedia elements, and the data interchange between the WBT and the learning management system. These are completed by 31 guidelines concerning the production process and the test-phase, separate guidelines in the form of a style guide, and other guidelines concerning the definition of learning objectives and special terms. The WBT presented in the following sections is subject to the guidelines, which were set up for the internal production of WBTs. The user-interface of the WBT is divided into three frames: the top frame contains the register, the middle frame shows the content and the lower frame contains the navigation. Guidelines define the standardized creation of the register and the navigation and thus guarantee the uniformity of the WBT. The appearance of the middle frame which contains the content can differ through the use of various types of multimedia elements. In this case the guidelines only have recommendation character regarding the creation of multimedia elements and of the background. The arrangement and designation of the respective registers within the register area, their contents and their functionalities were specified. The functionalities are differentiated into obligating, recommended, and optional functionalities. The definition of the colour, optic, and functionality of the navigation bar contributes to a uniform appearance. The appointment of a uniform layout supports a uniform look & feel and is at the same time an important orientation aid for the learner. (Schellhase, 2001)



+2.1.2 Internet protocols and services 9/37

Internet protocols	services
TCP/IP (Transmission Control Protocol)	
SMTP (Simple Mail Transfer Protocol)	electronic mail (E-Mail)
NNTP (Network News Transfer Protocol)	discussion forum
FTP (File Transfer Protocol)	file transfer (FTP)
HTTP (Hypertext Transfer Protocol)	WWW
	telnet

Due to the TCP/IP-protocol al classical internet services can be used in an intranet . [illegible] . The most important protocols are SMTP, NNTP, FTP and [illegible] management

FTP is the acronym for File Transfer Protocol

Figure 3: Screenshot of a WINFOLine-WBT

The screenshot shows that the content frame is divided into a slide-area on the left hand side and a text-area on the right hand side. The learner can choose whether he wants to look at both areas or only wants to look at the slides. An arrow beside the title symbolises that other pages of the WBT refer to this page (incoming, referential hyperlinks). The title is completed by the indication of the learning section and the section-specific numbering. Different types of hyperlinks are characterized by means of small symbols.

BEST COPY AVAILABLE

On a click on a semantic hyperlink a separate pop-up window is opened. The bar then appearing on the left hand side symbolizes that the learner is following an excursus, this means he leaves the sequential course structure and navigates independently. The following figure shows the production process of the WINFOLine-WBTs.

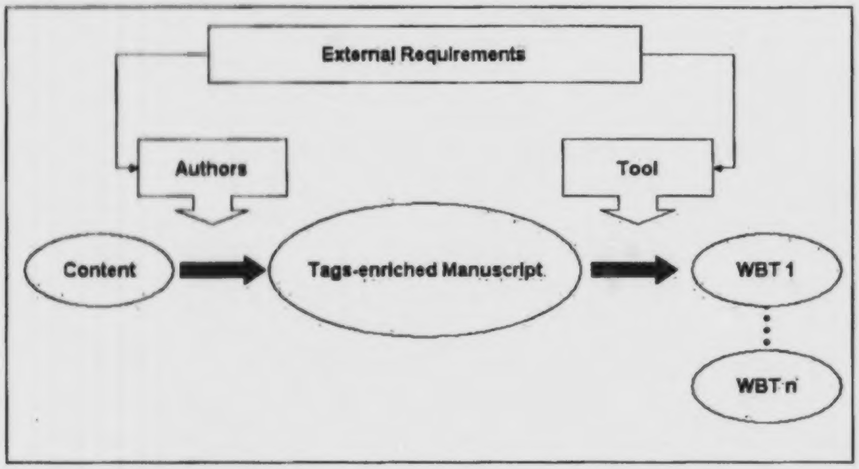


Figure 4: Production Process of WINFOLine-WBTs

For the production of a WBT the authors use WYSIWYG-editors. They have to employ some semantic tags. In this way the manuscript is automatically transformed into a WBT by a tool. This approach makes it possible to produce numerous variants of WBTs. Contents can thus be used several times (see Winand, 2002). The screenshot has shown a WBT that meets the specific guidelines of the elearning network WINFOLine. The WBT was produced by the WBT authoring tool VLEG (see Winand, 02). The authoring tool VLEG can be used to produce flexible und configurable WBTs. The VLEG helps to reduce the development expense for WBTs significantly. In addition, the maintenance process is simplified. The WBTs automatically have many sophisticated features and are especially well suited for Web-based learning.

Conclusions

This article has shown potentials and restrictions of WBT Guidelines. From our point of view, guidelines represent an important success factor for the production of high-quality standardized WBTs. Their development can be considered as a key success factor regarding the effectiveness of WBTs.

The definition of guidelines depends on the specific situation of the producer. The framework described in this paper contains several suggestions for the development of WBTs and can be of assistance in the project-specific development of guidelines. An optimum at guidelines is to be aimed at, taking notice especially of producers and learners.

Guidelines have to be developed continuously; they have to be adapted to changing internal and external requirements. Thereby international standardisation efforts should be paid special attention.

A Critical Discussion of Standards for Web-based Learning

Oliver Bohl, Dr. Jörg Schellhase, Prof. Dr. Udo Winand
Department of Business Informatics
University of Kassel
Germany
{bohl,schellhase,winand}@wirtschaft.uni-kassel.de

Abstract: Learning technology standards are increasingly gaining in importance in the field of Web-based teaching. At present, two standards dominating the market are taking shape. These are the AICC standard of the AICC organization and the SCORM standard of the ADL initiative. Up to now, only the AICC standard can be certified. But in the near future the SCORM standard will be certifiable, too. Based on the AICC and LOM meta data standards, the SCORM standard stands the chance to become the standard dominating the market. A number of restrictions are involved with the mentioned standards, though. This article examines general deficiencies of the mentioned standards, as well as the problems resulting from their application to learning management systems.

Introduction

Over the past few years several initiatives developed, at first in the USA, aiming at the standardization of computer based teaching components. This article focuses on the AICC standard of the AICC organization and the SCORM standard of the ADL initiative. Why are standards important for Web-based learning environments and technologies? Considering the increasing number of virtual learning environments, it is obvious that the same contents are processed several times for multimedia use because they cannot be found or used straight away. This is where standardization efforts start from.

Influential Factors on the Interface between WBT/LMS

LMSs offer tools which manage and generate different sorts of data. The term LMS can denominate simple course management systems as well as highly complex LMSs with extended functionalities. These additional functionalities include interfaces to other information systems as well as reports, registration, and online collaboration. (Hendricks, 2001, p.20) Web-based Trainings (WBTs) should work with any Learning Management System (LMS). For this to be possible, the exchange of data must work.

There are many authoring systems on the market to produce learning units with. The decision on a certain system often binds the vendor of learning content to that system. This is not surprising because some of the possibilities the individual systems offer differ considerably. Up to now, it is not possible to transport learning units between different authoring systems without any difficulties. Therefore, a future change of authoring systems correspondingly turns out to be difficult. This causes problems for developers of WBTs. The exchange of WBTs between different LMSs leads also to some difficulties. In this field as well has developed a multitude of systems in the meantime. But none of these systems has achieved a dominating position, yet. The selection is made on application-specific criteria. (Hagenhoff, 2001)

Requirements for Standardization

To facilitate the exchange of knowledge between different institutions, the content to be exchanged has to be standardized. The aim is to be able to use LMS components efficiently and independent of system environments, the authoring systems used, and further technical infrastructure.

The most important influential factors on the effectivity and efficiency of learning technology, and thereby on Web-based elearning, are aspects of the reusability of the content, the interoperability/ portability of the content objects, the recombinability of content, methods and specifications, the recontextualization of the content in various contexts, the flexibility regarding the granularity of the content, the simplicity to use the standard and the efficiency of a standard. (Pawlowski, 2001, p.58).

AICC

Having developed from the US-American aviation industry, the industry-wide standardization committee AICC has more than ten years of experience in the field of computer based learning and today deals with the development of interoperable learning technologies. AICC's guidelines define standards, which permit LMSs and WBTs to exchange data. These guidelines are developed continuously. It is the purpose of the AICC standard, to facilitate the development of WBTs independent of a concrete LMS. With the help of structure files, a WBT conforming to AICC can quite easily be integrated in a leaning management system conforming to AICC. Lessons of a WBT are launched by the LMS. According to the AICC specifications, the LMS and the AICC compatible lessons must have common interfaces for data exchange. Thus, the LMS has the ability to start learning content as well as to track the learner's progress.

WBTs and LMS conforming to AICC can be certified. The certification is limited to a period of two years and has to be renewed thereafter. The following paragraphs show in detail which data is defined by the AICC standard and how the data exchange is realized.

Communication between LMS and WBT

When starting a lesson, the LMS sends static learner data (e.g. the name of the learner), dynamic data (produced during the previous learning session) as well as messages and comments from the tutor. Lessons completed or aborted by the user send data to the LMS. This data is utilized for the analysis of the learning progress.

Data Groups

The AICC standard defines the following 9 groups of data:

- *Core data:* Core data contain basic data of the learner, the learning session, and the learning success. (AICC, 2001, p.63)
- *Lesson data:* This is where individual information for the next start of the lesson is stored. This data is drawn up during a learning session and is stored and managed by the LMS. Among other things, this is data about where a learner has left a lesson. It facilitates the learner's return to the exact position of that lesson. (AICC, 2001, p.77) Furthermore, the learner's way through a lesson is recorded.
- *Core data of the vendor:* Vendor specific data, necessary for some lessons. (AICC, 2001, p.193)
- *Comments:* With help from the LMS, the tutor can send help texts to the learner. (AICC, 2001, p.79) The other way round, the learner can write comments about a lesson to the tutor. In doing so, the position the comment refers to is sent to the LMS. (AICC, 2001, p.193)
- *Evaluation:* During learning sessions data about learner performance and his or her objectives status can be ascertained. (AICC, 2001, p.81)
- *Objectives status:* Objectives can be given in each lesson. It is recorded, whether the learner has achieved the lesson's objectives or not. (AICC, 2001, p.85). In addition, the achieved score and the required time are recorded. (AICC, 2001, p.213)
- *Learning data:* This group of data supports the adjustment of a learning unit to the performance of the learner. Thus, a learner can be offered a starting point according to his or her knowledge level. Furthermore, data on the learner performance is transferred. (AICC, 2001, p.91f.)
- *Student Demographics:* With the personal data available to the LMS, learning content can be individualized, e.g. by selection of the language. (AICC, 2001, p.98)

- *Student preferences:* This data group stores parameters chosen by the learner to adjust the learning environment. Among other things, this includes audio and video settings.

Course Structure and Level of Complexity

First of all, the definition of the course structure serves for the simple exchange of courses. The definition of the course structure stipulates the ways the learner can or must take through the learning unit. This information is stored in the structure files. The AICC standard defines four levels of complexity (1, 2, 3a, 3b). The levels show how complex a course is and which data the LMS requires. For level 1 information the AICC standard uses the six data groups core data, lesson data, comments, objectives status, learning data, and student preferences. While the evaluation data of level 1 refers to the lesson as a whole, the optional second level facilitates further, more detailed evaluation data on learner performance and behaviour. (AICC, 2001, p.137)

SCORM

The Advanced Distributed Learning Initiative (ADL) is financed by the US department of defense in cooperation with the White House Office of Science and Technology Policy and deals with the interoperability of learning courses. The initiative sees itself as an integrating approach and a coordinating institution. Coordinated by the ADL, the AICC, the IEEE (Institute of Electrical and Electronics Engineers), and the IMS (Instructional Management System Global Consortium, http://www.imsproject.org) have agreed on facilitating the cooperation of LMSs and WBTs of different vendors.

The ADL initiative mainly focuses on the design and development of sharable courseware objects. These shall be retrievable from a global information network in real time. (Fletcher, 2000) To achieve these goals, the ADL initiative formulated higher requirements for learning content like reusability, accessability, durability, and interoperability and, based on this, developed a reference model for sharable learning objects. (Dodds, 2001, p.1-3f.) This reference model, the Sharable Content Object Reference Model (SCORM), defines a Web-based model for the aggregation of learning content (content aggregation model) as well as a run-time environment for learning objects. The SCORM's purpose is to connect developing technologies and commercial as well as public implementations. (Dodds, 2001, p.1-4) SCORM focuses on key interfaces between learning content and different LMSs but is not specific about features and abilities of a certain LMS. (Dodds, 2001, p.1-31) An LMS must be able to track learner progress and to assess mastery of learning content. Among other things, this includes collecting learner profile information, delivery of content to the learner, tracking of key interactions and the performance within the content as well as determining the learner's next assignment.

The SCORM Run-time environment includes support for the communication with and the tracking of content in Web-based environments and is based on the run-time environment functionalities as defined in the AICC Guidelines for Interoperability. It provides mechanisms for a standardized learner tracking. The control flow regarding reusable and interoperable learning objects is managed externally by the LMS. But the LMS does not control the control flow within the learning objects. (Dodds, 2001, p.1-32)

SCORM Content Aggregation Model

The Content Aggregation Model supports the assembling of Sharable Content Objects (SCOs). It describes a nomenclature for learning content and references the IMS learning resource metadata information model, which for its part is based on the LOM specifications of the IEEE-LTSC (Learning Technology Standards Committee, http://www.ltsc.ieee.org). The Content Aggregation Model determines how learning content can be identified, described, assembled, and transferred from one LMS to another. In the SCORM Content Aggregation Model learning content consists of assets. Assets are electronic representations of media (e.g. text, pictures, sound, and websites). An asset can be tagged to a metadata document in an XML format, which supports the locating of assets and their retrieval from online-repositories. (Dodds, 2001, p.2-3)

A Sharable Content Object (SCO) represents one or more assets which use the SCORM run-time environment to communicate with different LMSs. An SCO represents the lowest level of content granularity which can be tracked by an LMS. An SCO should be independent of learning context to be reusable in different learning situations. Moreover, several SCOs can be assembled to form learning or exercise units on a superordinate level. To make a potential reuse practicable, SCOs should be small units. They can be the basis for sharable content repositories which facilitate their exchange. Only an LMS may launch an SCO, an SCO must not launch other SCOs. (Dodds, 2001, p.2-4) With the mechanism of content aggregation, content objects (SCOs, assets) can be assembled to form bigger learning units (e.g. course, chapter). This mechanism determines the structure and performance as well as the sequence of the individual SCOs. (Dodds, 2001, p.2-6)

The mechanism of content aggregation supports the reuse of learning content und reduces the dependency of a course on a particular LMS. The structuring mechanism of content aggregation is derived from the computer managed instruction (CMI) specifications of the AICC. (Dodds, 2001, p.2-102) According to the content aggregation description, the LMS interprets respectively processes the rules for navigation defined within the aggregation of SCOs. (Dodds, 2001, p.2-102) The navigation for the SCOs is determined by the structuring mechanism of the content aggregation and is not part of an SCO. It is the LMS which is responsible for launching the SCOs in the defined sequence in run-time. This is important because content would not be reusable, if it contained course context-specific information. (Dodds, 2001, p.2-7)

Metadata in the SCORM

The metadata of the SCORM is based on the IEEE-LTSC LOM standard and on the IMS metadata specifications. (Dodds, 2001, p.2-10) There are nine categories of metadata elements altogether: general metadata, lifecycle metadata, meta-metadata, technical metadata, pedagogical metadata, metadata concerning rights, relational metadata, metadata on annotations and classifications. For the SCORM, a number of metadata elements were marked to be binding. In addition, further specific metadata elements can be stipulated. With the help of the metadata elements, the learning objects to be managed can be described in a standardized way. (Dodds, 2001, p.2-11) Guidelines concerning the use of metadata should be defined based on the specific requirements of the respective organisation.

Analysis of AICC and SCORM

Fundamental objectives of the presented standards are the easy portability of learning content from one LMS to another as well as the reusability of learning objects. The easy portability of WBTs creates an additional benefit for vendors of learning content and LMSs because the high costs for portation are reduced. WBTs can exchange data with the LMS via standardized interfaces. Above all, the metadata model of the LOM standard integrated in the SCORM supports the retrieval of learning objects in varying constellations. AICC denominates the smallest unit which can be administered by an LMS as an assignable unit (AU). This corresponds with the SCORM's Sharable Content Object (SCO). In the following, AUs and SCOs will be summarized under the term learning module. If common characteristics of the AICC and the SCORM standards are adressed, the general term "standard" is used and if a distinction between AICC and SCORM is necessary it is made explicit.

Potentials of AICC and SCORM

An important advantage of standard conforming WBTs is that they are basically interoperable with all standard conforming LMSs. In addition, they can exchange important user data, metadata on learning units, and a variety of interaction data (e.g. choice of path, current position in the learning unit, comments/annotations, duration, scores) in a standardized way with standard conforming LMSs. The basic metadata of a standard conforming learning unit is transferred to the LMS in the form of files when the learning unit is delivered, so that this metadata does not has to be fed to the LMS separately.

When using standard conforming learning units, an LMS can offer learners a learning account. Learner scores can be managed course comprehensively in a standardized way via this learning account. Though with AICC the possibilities the learning account offers are limited because not the complete test results but only results concerning single basic questions/exercises can be transferred to the LMS. Furthermore, the learner can take a look at a table of his or her learning status relating to single learning modules at any time. Learning module-specific comments a lecturer has left for a certain learner can be displayed when the learning module is started. The administration of the current position in an individual learning module can be done by the LMS, so that this information can be transferred when the learning module is launched. Annotations/comments transferred from the learning modules to the LMS can be managed by the LMS and be presented to the lecturer in a well-structured form. For the AICC standard must be observed, that student annotations can be transferred to the LMS, but the AU cannot request them from the LMS again later. The diverse data, which according to AICC/SCORM can be transferred to the LMS facilitates the comfortable supervision of the learning progress. The LMS could offer aggregated representations of test results and which learning modules have already been worked on by how many learners. Learning histories of the learners could be managed. Tracking data, transferred from the learning modules to the LMS, could be presented to the tutors in different views, so that they receive valuable indications concerning the further design of content. A long time on average spent on certain content pages could indicate that the content has to be processed better. Again, a low number of accesses on certain pages could indicate a lack of interest in the content.

Difficulties with AICC/SCORM conforming LMSs

The statements above basically show which potentials are connected with the use of standard conforming LMSs. But AICC and SCORM do not determine the use or processing of data transferred from learning modules to the LMS. In an extreme case it is possible that an LMS receives interaction data from a learning module but does not store it. This means that for the decision on a certain LMS it is not sufficient to see that the LMS is conforming to SCORM or certified by the AICC. It should be exactly analyzed how the AICC/SCORM standards have been implemented in the LMS and what the resulting possibilities for learners and lecturers are. AICC certified or SCORM conforming LMSs, which only provide minimal information for the learner (e.g. number of launches of the learning module, duration of learning with a learning module) for standard conforming learning modules and do not support the lecturer with evaluation data at all, fulfil the formal label of being AICC certified or conforming to the SCORM but by far do not use all the possibilities these standards do offer. Astonishingly, these statements are not as trivial as they may seem at first glance. Even some LMS market leaders use the possibilities offered by the AICC/SCORM standards only insufficiently.

Deficits of the AICC and the SCORM

In addition, there seems to exist a conflict between the principle of reusing learning modules and the classic web paradigm of using links to show relations between content. Neither in the AICC nor in the SCORM it is possible to realize hyperlinks from one learning module to another. The reason given for that is that it otherwise would not be possible to realize the principle of reusing learning modules. At the same time it is advised to produce as small learning modules as possible. Thus, referential links are only possible locally within the learning module and to external websites. Structural hyperlinks, however, are managed by the LMS. Each learning module has to be explicitly started by the learner via a menu on the LMS. Even an explicit textual reference within a learning module, referring to another part in another learning module, would not be advisable because it would also contradict the principle of reuse. In our opinion, and in contrast with the argumentation of the AICC and the SCORM, these standards could be extended in the way that at least a partial referential linking even between learning modules is possible. During the combination of learning units invalid learning module comprehensive hyperlinks and further referential text parts would have to be automatically recognized and filtered, though.

Theoretically it is possible to develop WBTs conforming to the AICC/SCORM consisting of merely one learning module. In this case, any number of hyperlinks can be integrated and WBTs can be developed, which support explorative learning. Indeed many developers follow this path currently. The described variant limits the possibilities for reuse provided by the AICC/SCORM, though, and many of AICC/SCORM's possibilities remain unused. The LMS would receive and manage only some basic metadata (course name, course developer, etc.) and annotations/comments (unit-specific) as well as path information. The LMS does not have any information about the course structure and the administration concerning the learning status in learning modules is inapplicable. At least the authentification mechanism can be realized through the AICC/SCORM standards.

The previously put forward demand to extend the AICC/SCORM standards is important because the current limitations of the AICC/SCORM lead to standard conforming WBTs either not being able to make full use of the possibilities of the web paradigm or the AICC/SCORM. If the AICC/SCORM standards were extended appropriately, the objective of reusability could be supported better, the various advantages of the AICC/SCORM standards could be reached, and with the technique of referential linking, high-quality and learning module comprehensive functionalities could be integrated in the WBTs to better support the learning processes.

Conclusion

This article has explained the potential benefit of standards in the field of learning technology by example of the AICC and the SCORM. The main advantages are in the field of portability of learning content, the standardized communication interface between the LMS and CBTs/WBTs as well as in supporting the reusability of learning objects. A wealth of possibilities for support connected with the standards on the part of the LMS were shown clearly. But the article has also shown the basic difficulties of standards and the weaknesses of LMSs concerning the full use of the possibilities connected with standards. The effort of standardization should not too rashly be viewed negatively. The development of standards is a continous process. But in the framework of further developments, the criticized aspects mentioned above should be taken into consideration.

Abstract: Today, although much debate surrounds the effectiveness of including graphics in web-based distance education courses, most course authors agree that such courses should productively engage students so that quality learning actually occurs. But just what is productive engagement in a world of electronic communication and text? This paper offers interested readers with a possible answer to this question by providing evidence that the use of graphics can enhance on-line teaching. The evidence includes a description of: the use of four different visualization types and techniques as instructional tools, the positive perceptions of 22 undergraduate students towards the use of these types and techniques, and the beneficial impact of their use on learning outcomes in an on-line undergraduate science course.

Introduction

In 1998, the Department of Poultry Science at the University of Arkansas, Fayetteville was awarded a United States Department of Agriculture (USDA) Higher Education Grant to address a growing instructional void in introductory poultry science. The objective of this project was to address the demand for this instructional need by developing two web-based poultry production courses that would cover the management of broilers, turkeys, breeders and layers. The Internet was chosen as the platform for course delivery because it is asynchronous and may be accessed from any connected site around the world. A content expert, an instructional designer and a graphic artist carefully reviewed a variety of instructional techniques and determined that a combination of visualization types and techniques could aid the learning process in the proposed on-line courses. Their unique instructional interface combined the use of static graphics, hypertext pop-ups, animation and concept mapping exercises to establish greater interaction or engagement between the students and course content. After the first course (Broiler & Turkey Production) was developed and implemented, the impact or benefit of these visualization types on the learning process was explored through document analysis and student interviews within a case study format.

Theoretical Underpinnings

The choice to use visualization as a method to engage students was based upon a review of two separate bodies of research and corresponding literature that assert that the visual representation of information increases a student's ability to learn in text-based environments. The first body of research addresses visual literacy, the second body addresses the development of mental models.

In regards to visual literacy, Levie and Lentz (1982) provided a comprehensive meta-analysis that addressed the effects of illustrated texts on learning by summarizing the results of 155 separate experimental comparisons.

> Forty-six of those (155 studies) studies compared learning from illustrated text material versus *(learning) from text alone*. In all but one of these 46 cases, the group mean for those reading illustrated text was superior to that of the group reading text alone...in 39 of the 46 comparisons, the difference was statistically significant...and the average group score for the illustrated-text group was 36% better than for text -alone groups (Levie & Lentz, 1982, p. 198).

A deeper examination of the impact of the use of graphics and illustrations on learning from textbooks was detailed by Braden (1996) and Rieber (1994). These authors both discussed Paivio's 1971 Dual Coding Theory of memory and cognition in detail. In essence, Dual Coding Theory postulates that humans encode information to long-term memory both verbally and visually, and that verbal concepts are hung on nonverbal pegs in memory; i.e., imagery is the effective variable in recall of concrete verbal/written information. Further, "this means that if some piece of information is coded both visually and verbally, the probability of retrieval is doubled" (p. 113). Dual Coding Theory ties nicely to the research on mental representation as discussed by Winn and Synder (1996).

In 1996, Winn and Synder asserted that cognitive psychology and science research may be divided into two major categories which link visual imagery and the creation of mental models to learning: mental processes and mental representation. According to Winn and Synder their review of the literature in this area supports the argument that individuals learn new information and solve problems by creating their own visual metaphors or envisioning complex processes. According to their analysis of Salmon's research, human thinking "uses various symbol systems as tools" to gain new knowledge (p. 117).

Designing Instructional Graphics

The effective design of instructional graphics is best achieved when it is anchored within a specific learning theory. Thus, it is important to note that while Levis and Lentz's (1982) meta-analysis may be viewed independently from any specific learning theories, Dual Coding Theory and mental representation are obviously best understood when related to cognitive and constructivist learning theories. An insightful theory-based guide that addresses these issues was published by Lloyd Rieber in 1994. In his book, *Computer, Graphics & Learning*, Rieber suggested that Gagnes's events of instruction support five applications of graphics to teach that lie within the cognitive-constructivist continuum: "cosmetic, motivation, attention-gaining, presentation and practice" (p. 45). Applying Gagne's events of instruction, Rieber asserts that content experts and instructional designers should include graphics in instructional materials in conjunction with verbal/written content to serve precise instructional functions and only if they fulfilled specific instructional objectives. Further, Reiber asserted the function of a graphic may be arbitrary or may be used to create a realistic representation or an analogy. Representational graphics depict reality or a simplified version of it as seen in Figures 1 and 4. Arbitrary graphics can be graphs or charts, etc. or may depict a mental model of a system or phenomena as seen in Figures 2, 3 and 5.

Rieber (1994) also asserted that the research on visually literacy can be viewed according to Blooms' Domain of Learning Taxonomy. Reiber argued that cosmetic and motivational graphics impact the affective domain while attention-gaining, presentation and practice graphics impact the cognitive domains. Further, effective cognitive domain graphics gain and focus student attention selectively. I.e., effective attention-gaining and presentation graphics help students to filter out external distractions, but should not be a source of distraction or cognitive overload themselves. (Cognitive overload happens when too much information is presented all at once.) Effective practice graphics support students in higher-level cognitive processes such as the integration of new information into prior knowledge.

Rieber's review of research concerning the use of instructional animations revealed that little research has been done in this area. However he was still able to make some important points. Rieber asserted that as with static graphics, animations should be used "to demonstrate or elaborate concepts, rules or procedures" (p. 50). In addition, he highlighted two special effects produced by this type of graphic based upon his own research in this area. Animations are able to show changes over time and changes in direction or the trajectory of an object or phenomena.

This paper focuses on the use of graphics for attention-gaining, presentation and practice. Another important aspect of the use of graphics in web-based courses that is not addressed by this study is user interface design. Navigation disorientation negatively affects learning outcomes and can be very frustrating to for the learner. This topic is extremely important and as such should be examined separately.

Description of the Visualization Types and Techniques

Effective Attention-Gaining Presentation with Static Visuals, Hypertext Pop-ups and Animation

The following examples represent a sequence of web pages in a module within the first course that covers physiology. This module teaches students about temperature regulation in poultry by using static visuals, hypertext pop-ups and animation.

Figure 1 illustrates the two basic or primary features of poultry physiology important to homeostasis (the ability to maintain a constant body temperature) through a static graphic. In this case the design of the graphic was intentionally kept quite simple in order to focus students on basic pre-requisite information/knowledge. The graphic visualizes the most important facts presented. The student's instructional objective was to grasp that poultry, like other mammals, are warm-blooded and must maintain a nearly constant inner body temperature (around their internal organs, or core).

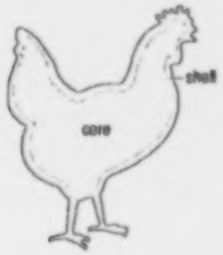

Figure 1: Static Visuals

Figure 2 guided students to build a deeper understanding of the physiology of homoeothermic animals by engaging students with hyper-text pop-ups windows. Clicking on each of the zones activated the appearance of a second image that contained additional information as seen in Figure 3. A bird's thermal environment may be described by several temperature zones. Different species' physiological reactions to a particular temperature may differ, but many animals go through similar behavioral and physiological changes as temperatures increase or decrease. The student's instructional objective was to describe each of the temperature zones to which poultry may be exposed, listing the thermoregulatory mechanism(s) that might be used, including specific examples.

Intolerably Hot Zone

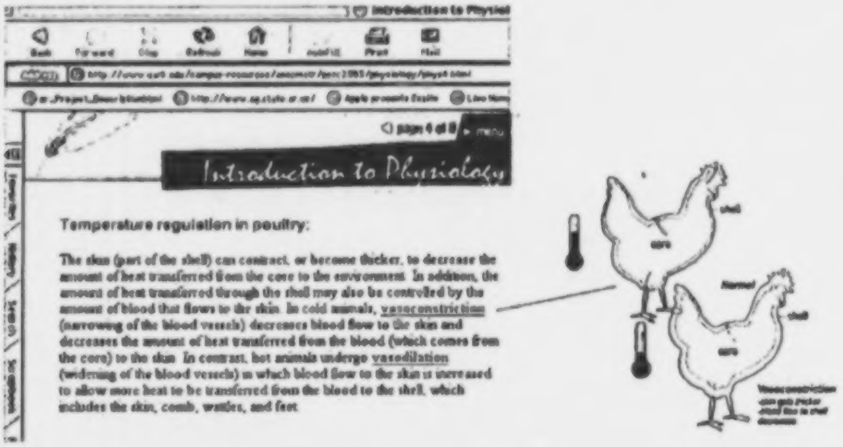
In this zone, an animal has used up all active and passive thermoregulatory mechanisms to stay cool. The animal cannot sustain its body temperature for very long, and death will eventually result.

Figure 3. Pop-up Hypertext/Second Browser Window for Intolerably Hot Zone Bar
(A mouse click on the red bar in Figure 3 causes this information to pop-up along with Figure 3.)

Figure 4 presents two important definitions with hypertext pop-up windows and animation. A mouse click on either of the two hyper-linked terms highlighted in blue (vasoconstriction and vasodilatation) activated a second pop-up browser window that revealed a graphic illustration of the concept. In this case the pop-up illustrations were animations. These hypertext pop-up animations emphasized key concepts by prompting students to attend to and explore important terms and definitions. The student's instructional objective was to define the terms vasoconstriction and vasodilation, and indicate how heat flow from the core through the physiological shell is impacted by these processes. Each of the simple two part animations revealed a progression in temperature change specific to the each of the two terms presented. The animations presented students with the normal state of poultry at two temperatures. A graphic representation of a thermometer changed to correspond with physiology changes in the poultry as the temperature changed. The use of animations to teach these concepts provided an excellent opportunity for the students' to learn an invisible and complex scientific phenomena that could not be demonstrated otherwise. In this case the animations are able to show changes over time and changes in direction or the trajectory of a phenomena.



Temperature regulation in poultry:

The skin (part of the shell) can contract, or become thicker, to decrease the amount of heat transferred from the core to the environment. In addition, the amount of heat transferred through the shell may also be controlled by the amount of blood that flows to the skin. In cold animals, vasoconstriction (narrowing of the blood vessels) decreases blood flow to the skin and decreases the amount of heat transferred from the blood (which comes from the core) to the skin. In contrast, hot animals undergo vasodilation (widening of the blood vessels) in which blood flow to the skin is increased to allow more heat to be transferred from the blood to the shell, which includes the skin, comb, wattles, and feet.

Effective Practice with Concept Mapping Exercises

Figure 5 shows a detail of a concept map. Concept mapping exercises were imbedded into the course's content where ever applicable, to force students to articulate and reevaluate their knowledge by creating a mental model. These exercises represent graphics used to promote higher-level cognitive

processes. Concept maps graphically illustrate relationships between ideas and their use in traditional classroom settings has been shown to greatly aid students in the process of restructuring their own knowledge and/or expanding their own conceptual understanding (Novak & Gowin, 1984; Novak & Musonda, 1984; Kennedy & McNaught, 1997). Within a concept map, two or more concepts are linked by words that describe their relationship. A concept is "a perceived regularity in events or objects or records, designated by a label" (Novak & Wandersee, 1990, p. 29). The student's instructional objective was to design a concept map that described the transitions a bird undergoes in each of the temperature zones, including references to passive and active thermoregulatory mechanisms, using real-world examples of different types of heat transfer.

Sample & Methods

The developed course (Broiler & Turkey Production) contained eight sections of content presented within a modular format: historical insight, hatchery operations, brooding management, grow-out management, housing, physiology, introduction to nutrition, and financial aspects of poultry production. As stated previously, the visualization examples in this paper were all drawn from a single module that covered physiology. This module was chosen as the focus of this study because it contained the most difficult content within the course. Twenty-one students volunteered to participate in the case study conducted on the physiology module. All twenty-one students completed pre- and post-content knowledge concept mapping exercises and six students were chosen to participate in the nominal group interview process based upon their concept mapping exercises. The purpose of the interview was to: examine user patterns and probe student perceptions and attitudes. The sample in this study placed limitations upon the type of interview process that was conducted. A true focus group could not be established because the participants knew each other and were not randomly selected. The choice of a nominal group interview process however was not seen as detrimental to the outcome of this study; nominal group interviews are particularly productive when researchers are seeking to provide consensus or recommendations concerning alternative solutions (Krueger, 1994, p. 19).

Student Perceptions of the Visualization Types and Techniques

All six of the interview participants asserted that the incorporation of static graphics, hypertext pop-ups, animation and concept mapping exercises within the poultry physiology content successfully increased their interest and engagement by causing the courseware's print-based interface to take on the

BEST COPY AVAILABLE

role of the teacher or instructor. This is particularly noteworthy as one of the primary goals of this study was to determine if the use of graphics could establish greater interaction or engagement between the students and course content to compensate for the decreased dialogue between the students and instructor common in distance learning situations. For example, Lindsey talked about how the various components helped to take the place of face-to-face contact with the instructor by stating: "...the icons helped tremendously because if you don't understand something you could go into those icons, and it gave detailed information about whatever he [the instructor] may actually be talking about. If you don't have a teacher and you can't ask him...for some of the students in ACTA [the Arkansas Consortium for Teaching Agriculture] schools [pause] I know take some of ours classes and stuff [pause] if they don't have that, then it would be kind of difficult [pause] if you don't have a teacher there…so the icons helped tremendously."

Further, Mickey elaborated on how various visualizations caused the content to be more dynamic by saying: "The diagram [Figure 2 and 3] that he [another student/Ken] mentioned was really, really helpful. You could click on the different parts [temperature zones shown in graphic form] and get information, but there was also a line showing [pause] how they [the poultry] were able to change their body temperature. I memorized that line, and that way I did not have to memorize every zone. Also you could click on vasodilatation and vasoconstriction on another page for further details..."

In specific regard to the use of concept mapping exercises, although only three of the 6 interview participants specified that concept mapping was a useful tool that enhanced their learning experience, all of the participants asserted that completing the concept mapping exercises required them to: increase their interaction with the course content and re-think their ideas about poultry physiology. For example, Hank affirmed the impact of concept mapping on his learning experience by saying: "It was useful. It was definitely useful…I would have to say as far as the temperature changes and things like that go... "

And Lindsey remarked on the differences between learning from the content alone and learning by creating concept maps by saying: "I think [pause] just basically putting everything into an organized manner [pause] if you just read the material than you are just getting a whole bunch of material, but when you do the concept map it showed like what you started with and what you ended with [pause] it helped [me] to understand the material."

In addition, the following comments indicate that it was not just one particular kind of visualization, but the combination of the other visuals used with concept mapping that created a better on-line learning opportunity. Hank describes his use of a hypertext pop-up graphic that showed various temperature zones during the post-concept mapping exercise by saying: "Whenever I read through the stuff on the web on that certain page that told all the temperature zones and how [pause] what effect it had on each one [pause] that was basically how my concept map was set up. It had the chicken in the middle, and then it had all the temperatures branching out from that and telling if it was passive or active or neither or both [pause] and each of the temperature zones and how they effected the chicken..."

Tom also elaborated on how the combination of graphics within the courseware helped him to learn temperature regulation in poultry by saying: "When doing the concept map, I just noticed throughout the physiology section that they would have words highlighted if they were scientific terms, and when you clicked them a pop-up screen would come up. Sometimes it would be a graph and sometimes it would be a definition, but it would pretty much explain it."

Concept Mapping, Changes in Mental Models & Learning Outcomes

A quantitative scoring scheme designed by Novak and Gowin (1984) was used to evaluate two concept mapping exercises administered before and after the students studied the on-line poultry physiology materials (Edmondson, 1999, p. 25). The goal of this evaluation was two fold: revealing changes in student mental models of temperature regulation in poultry, and as an alternative method of assessment. In contrast to other types of graphic organizers, Novak's concept mapping emphasizes the importance of specifying the links between key concepts, including cross-links across branches of any given hierarchy and adding examples to anchor concepts to the real world (Trowbridge & Wandersee, 1999). The scoring scheme is shown in Table 1. Changes in concept mapping scores are shown in Table 2. Please note that the concept map scoring data was analyzed from a qualitative rather than a quantitative viewpoint as attempts to establish the reliability and validity of concept maps has been shown to be problematic in previous studies. In addition, when reviewing the scoring scheme please note that the number of possible answers for each category was established using an expert concept map as a guide, however the expert map was not made available to participating students at any time during the study. The highest possible score was figured by multiplying the number of possible answers by the point value. The concept mapping exercise data takes the evaluation of the visual types and techniques used in this project a step beyond student perceptions by actually measuring learning outcomes. This data strongly indicated that student knowledge of introductory poultry production increased significantly because concept mapping exercises were imbedded into the courseware. Concept mapping acted as a tool for problem solving through the creation and invention of student mental models. Further, the student interviews plainly showed that students used other visualization types and techniques in order to complete their concept mapping exercises. Therefore it can be asserted that the inclusion of certain types and combinations of visualization positively impacts learning outcomes in web-based distance courses.

Implications and Future Directions

A triangulation of all of the data gathered this study indicated that the inclusion of certain kinds and combinations of visualization types can be used to productively engage students and thereby positively impact learning outcomes for web-based courses. The benefits of most of the visualization types used in this study as teaching tools have been clearly established by previous studies. However, this study is unique as it examines the use and impact of traditional graphics used in combination with animations and concept mapping on student engagement and learning outcomes within web-based courses. Therefore, the findings of this study are significant.

To place this study further into context an additional review of the literature concerning the instructional effectiveness of web-based courseware was conducted. This review revealed that only a few good studies of this nature currently exist. The most significant of these studies evaluated teaching practices within 486 educational web sites and concluded that use of the web caused teachers to choose ineffective teaching methods; of the courses sampled only 5.0% provided students with opportunities for problem solving, only 4.6% provided opportunities for creation and invention, whereas 52.5% left students with few options other than rotate memorization (Mioduser, Nachmias, Lahav and Oren, 2000, p. 63). Mioduser's, et al study did not examine web-based distance education courseware specifically, however their findings are still applicable to the study presented in this paper. Mioduser's, et al conclusions strongly support the argument that the courseware described in the preceding paragraphs was effective because it provided students with tools that prompt higher-level cognitive processes, such as problem solving and creation/invention.

In conclusion, the study presented in this paper is a single case study and as such cannot be broadly generalized. The results of one case study may be insightful, but the results of a series of case studies that examine the same topic would be more conclusive. Further case-based evaluation of the use of the visualization types and techniques presented in this paper is currently underway and will provide the opportunity for a meta-analysis of multiple case results.

Elearning translates to experiential learning
In a
Communication theory class

Mukhbir Singh
E-mail: mukhbir@unforgettable.com

> What you have discovered is receipt for recollection, not for memory. And as for wisdom, your pupils will have the reputation for it without reality; they will receive a quantity of information without proper instruction, and in consequence be thought very knowledgeable when they are for the most part quite ignorant (Plato, 1973).

It is not of much use to see literacy as just reading and writing, ignoring the advanced demands that modern, industrial cultures have routinely placed on students in terms of these skills. It is not realistic to expect that merely by "reading" (one sided-engagément) of the text, students should be able to understand something of which they have little or no prior knowledge, or that all people and not just a privileged few, should be able to create texts that others may find useful and appealing. In a certain way, the heart of this issue lies the complexity of the connection between literacy and technology (Tuman, 1996). To understand this connection we must examine some of the common pedagogical practices and try to develop an understanding and see what is a viable and effective approach in the fast paced techno-industrial society of today.

The traditional model of pedagogy has its roots in linearity. This probably came about in the literate world because of the reproduction of language, as a means of instruction, in the form of a book. The advent of the printing press was a major step in this direction. As literacy changed, from its original oral to the written form in pedagogical practices, linearity became an important asset for the reproduction and creation of knowledge. This model of pedagogy is what we commonly use in the classroom today and is called Instructionism. Linearity over the years became a standard method of teaching as well as the construction of knowledge. This model therefore gave rise to the belief that knowledge could be transmitted through a linear method of instruction and is most common model today.

On the other hand, the constructionist approach to learning has its roots in the constructivist pedagogy, which claims that knowledge cannot be transmitted to a learner; rather the learner needs to construct knowledge by her/his own. The constructionist approach stresses the physical construction of artifacts by learners as a crucial method for them to be able to construct knowledge in their minds. This approach implies that the task of learning largely be left in the hands of the learner. She/he is free to structure knowledge as they maybe inclined to, even if it is in the wrong direction. This particular situation has significance from the point of view of creation of knowledge and understanding of theoretical concepts, in particular, concepts related to communication theory.

One method of instruction, therefore, could use the instructionist approach to teach these concepts, which are often described as difficult and abstract by undergraduate students. The other method could use the other, constructionist approach, to teach these concepts to these students. However, in the absence of feedback, students could likely construct a different meaning of theory(ies). To overcome the shortcomings of both pedagogical approaches, an integrated approach to teaching communication theory may prove to be more useful. The purpose of this paper is to analyze feedback given by students of a communication theory class, which uses an integrated approach to help students learn the concepts of communication theory. This analysis will seek to determine how this integrated approach helps students understand communication theory, if at all it does help them.

Before beginning the analysis, it is necessary to describe the pattern of teaching that is followed. The class clearly consists of two parts, the first part being the instructionist part. In this part of the class, the students learn about communication theory by reading about it in a prescribed book as well as scholarly articles. The students are also tutored through lecture/exercises. In addition to this, in order to mark the progress of the student as well as to ensure that they are keeping up with the text a short quiz is given to them at the beginning of each session. These quizzes as well as the exercises serve the function of feedback to the students in the class. Feedback is associated with linear instruction (Instructionism), which typically has the following sequence: students are presented with information, followed by a question. After providing an answer, a feedback is presented to the students. The continuation of the learning path is determined by structured interaction. In the second part of the class, the constructionist part: the part where students learn how to represent theory using hypertext. Hypertext, by the original definition, is the opposite of the traditional linear text. Hypertext can be browsed in a non-linear way, that is, it does not require the user to follow by the default sequence of words, sentences, paragraphs, and so forth. Historically, designers of hypertext for educational purposes have used the notion of non-linear text not only with regard to textual and other media delivered in their program, but also the structure of the instructions embedded within the program(s) (Spoehr, 1994). This allows learners to freely navigate throughout the various resources of the program, according to curiosity, associations, or any other motives they might have. However, in the structure of this class the learners were not given a hypertext program to browse through instead it took it one step further by making the students develop their own hypertext, in the form of web pages for the World Wide Web, to represent the communication theories they had learnt.

The objective of this part of the course was to let the students construct their own hypertext pages as per their thought processes. The students were free to use any format for the development of an argument for explaining the concepts according to a theory of their choice. This did not mean that the students were left to their own devices to develop their hypertext pages and the links to other pages. They were tutored by a group of peers who had already taken the course, as well as the instructors. The objective of this tutoring was not to focus their thoughts in a linear structure but rather to focus on helping the students developing their hypertext so that it did not miss out any of the finer nuances of the theory that they were working with. This tutoring, by the peers and the instructors, serves the function of feedback as in the instructionist model. It becomes relevant to integrate it in the constructionist model so that the paths the students followed, in setting up their hypertext pages, lead to the important places and they did not miss out on relevant information and/or contradictory information, which could confuse them. This process is meaningful since the student is actively engaged in thinking about the topics in the theory that they were working with. In the absence of feedback, misconceptions could occur in the students minds about their construction, if for example, it turned out to be inaccurate or irrelevant (Phillips, 1995).

This feedback mechanism serves as a connecting link between the two pedagogical approaches. However, the type of feedback differs according to the approach. While feedback in the instructionist mode serves a corrective function – it is an indicator to the student to fill a gap, which may exist. On the other hand, feedback in the constructionist approach is contingent on content more than on learning objectives. This shift of focus helps shift the students' attention to content of the hypertext pages thereby encouraging them to construct their own version of knowledge – the theory that they are working with. Feedback, in this way occurs at each step of the learning process. This enables the students to move from the instructionist mode to a constructionist or hypertext mode when feedback fades out. It works in the other direction too -- feedback appears, giving the students an opportunity to move back into an instructionist mode when required. The students also make use of an Elearning software package called Blackboard to exchange notes, HTML codes, set schedules, and coordinate the presentation of hypertext, within their group(s).

Teaching the students to use hypertext in formulating their own learning, in one context, involves the use of computers and broadly speaking technology. Hypertext is created using HTML (Hyper Text Markup Language)for creating pages for the World Wide Web. The use of technology in society has its critics and supporters. The supporters of technology have been at the forefront of introduction of computers in the classroom. Whereas, the critics have constantly been at loggerheads with this approach. The most notable being the Unabomber who modeled his critique of technology, given in his manifesto, based on the work of Jaques Ellul. However, the Unabomber manifesto uses the word "computer" frequently in connection with "control" and "technology." Nevertheless, the objectives of this mode of instruction are a step towards reducing the instructors control over the construction of knowledge by learners. By using technology in a productive fashion a synthesis of two approaches encourages the student to test her/his creativity in organizing knowledge, as they feel fit. Therefore, the critique of technology as set forth by Ellul is not relevant in this case. Ellul envisioned widespread social destruction by the use of technology but, he based his observations on the existing state of technology in the 1960's and then extrapolated its linear trend, not accounting for social evolution or economic growth and prosperity. Ellul could not envision the redistribution of technological power, allowing individuals to publish content on an equal footing with large organizations (1964). The use of hypertext is empowering for the students in the classroom as it enables them to find a new voice and encourages them on a road to independent learning.

Another objective of this class concept is to encourage the students to write their own conception of communication theory. This is done to encourage students to be involved in the text and write to learn. This follows from the movement of writing across curriculum (WAC). Traditionally there is little time devoted to writing by the student because this was reserved for a language class. Writing across the curriculum believes that writing should not be its own subject; rather writing is a way for students to understand all subjects (Hill, 1992). This phenomenon of writing as mode of learning can be traced to two closely related movements in American education: the process-over-product movement and the reemergence of cross-curricular writing programs. The rise of new rhetorical scholars in the 1960's the process movement gained momentum. This led to a fusion of rhetoric with psychological and linguistic theories of creativity, composing, and problem solving. Many of the "new rhetoricians" were interdisciplinary, merging linguistics, philosophy, literary theory, communication theory, and cognitive psychology with rhetorical theory and writing instruction. This made possible the link between scholarship and process-over-product approaches. Using this linking approach, we encourage students to write their own conception of theory. Thus, writing and learning becomes a different project when the objective is to promote the understanding of the discipline. The high number of published accounts of successful classroom practices based on a writing as a mode of learning suggests that such practices offer the potential to transform the classroom environments (Ackerman, 1993). This methodology in actuality stimulates the thought-expression dialectic and encourages the student to construct a balanced view of knowledge of the discipline. It encourages them into self-expression through writing and leads them sequentially and by self-indexing into the public world of formal discourse.

One of the objectives of the course is to promote independent and experiential learning, thereby constructivism, amongst the students and move them away from the standard pedagogical mode of Instructionism. To know more about this the students are encouraged to write a self-assessment report for extra credit. Analyzing these reports reveals a considerable thought that goes into writing them. One student for instance said:

> "I have seen that I have been able to understand these complex (communication) theories, design a web page, talk about them with others outside of class; I have been able to do all of this on my own. If you had asked me if I would have been able to do this at the beginning of the quarter, my answer would have been a simple "NO!". I am pleased with my growth as an independent student, and I plan to take what I have learned and apply it to everything I do in life."

There are other criticisms of the use of technology. There is a feeling that the much-touted literary revival is a myth. People who used to talk to each other, even on the phone, now use e-mail. What really gets churned out on e-mails and web-groups is second-rate literary stuff (Stoll, 1995). Nevertheless, e-mail has been found to increase interactivity in discussions amongst students. In terms of successful learning, these students need a tutor's guidance but this guidance should treat them as mature people (Marttunen, 1998). In the design of this course structure, the students were given guidance at the multi-levels, from their peers, as well as from the instructors. This multi-level mentoring has its rewards in helping the students develop into independent thinkers while being team players. One student's comments read:

> "I believe that my independence has really blossomed. During the first three web-pages, I almost always ended up calling another member of my group or our tutor in a state of panic about what I had done wrong. I can now gladly say that I did the last two pages completely on my own, and what an amazing feeling that is! Along with independent learning, I have realized how to be an independent worker while working within a group."

The unfortunate part is that pedagogical practices that use technology for, or to assist instruction, do not attempt to use the possibilities of the technology to the full. They could be more effective and economical using standard print. A lot of them are a mixture of linearity and explorations, not very different from practices that existed in the print form about twenty years ago. They fall short of the desired expectations because they do not follow some basic principles of educational programs: (1) Active participation, by learners, in the learning process; (2) Immediate knowledge of results and corrective feedback; (3) Avoidance of excessive errors on the part of the learners (Romiszowksi, 1988).

In the experience of conducting this class, which makes a strong attempt to integrate, both Instructionistic and Constructionistic principles, the results are quite encouraging based on some of the comments that we have seen earlier. The boost in the self-confidence of the students, as stated in their self-assessments is a strong indicator of this. However, it is necessary to point out that these assessments were done by the students for an extra credit so they could be affects by the bias of getting a higher score. Although, some of them are quite candid in expressing their remarks, which reveal their frustration at not being able to sort out some glitches in the technology which is being used:

> "Words can't even describe the level of stress that I have right now because of this stupid fetch program. Because it is not directly linked to the oak (the Web Server for the university) system, it takes forever to get anything from my public file. I understand that is an educational experience you want all to participate on, but let me tell you, this not an option for Mac people (Macintosh users) if they do not have dial-net."

Since then every effort has been made to make these technical problems not interfere with the learning. In reality, however, these kinds of problems are a little window to the professional challenges that the students may face once they leave the university and pursue their careers. It is a kind of preparation for them not to expect that all things would work smoothly at all times. On the other hand, however, this kind of a pedagogical practice makes the student dependent on technology to a large extent. The teacher at this stage appears to be more of a technician. What the student wants at this stage the teacher may not be able to provide. This is the kind of criticism that is being pointed towards technology in the classroom. Education, as Talbott (1995) interprets Papert, needs to be integrated with life, put fun into exploration, learning, and the value placed on abstract reasoning is a major obstacle to progress in education. Although these comments are based on the issues faced by educators today, they are however relevant to this study. The students do start being dependent on the willingness of the computer to place its mimicking intelligence at their service and sometimes may diminish their intelligent capacity to cope.

Through the integration of Constructionist practices with standard Instructionist pedagogy using technology, a very strong attempt has been made to help forge a different and quite distinctive pedagogical strategy to overcome some of the issues that limit both methods, Instructionism and Constructionism, individually. The results of this strategy are quite encouraging and constant effort is made to enrich the creation, exploration, and learning of knowledge of communication theory.

Abstract:

The purpose of this paper is to analyze feedback given by students of a communication theory class, which uses an integrated approach to help students learn the concepts of communication theory. This analysis will seek to determine how this integrated approach helps students understand communication theory, if at all it does help them. This paper draws upon the scholarship of teaching and learning to analyze the emergent situation in the class room. The students make active use of Blackboard – an eLearning tool to facilitate interaction amongst themselves as well as the instructors. The paper focuses on the impact of such technologies to supplement pedagogical techniques in making them more constructive and effective.

Communication and Collaborative Learning at Work: Views Expressed in a Cross-Cultural E-Learning Course

Abstract: This study focuses on the prerequisites for successful communication and collaborative learning in a large multinational company experienced by human resource development (HRD) practitioners who participated in a cross-cultural e-learning course. The participants were Finnish and Chinese employees (n=17) who used an asynchronous web-based tool to study adult education in a virtual university course. The web discussions of the one-year university course were used as a material for this study. The discussions were analysed by the phenomenographic method. On the basis of the analysis three main themes concerning communication and collaboration at work could be identified: 1) prerequisites for collaborative activities, 2) cultural differences, and 3) the role of management. We discuss the implications of these aspects for the development of e-learning solutions for professional and organisational development.

Introduction

Technological progress and changes in organisational infrastructures have increased the significance of collaborative learning for professional development. How knowledge is constructed, shared and communicated in organisations and how teams and organisations learn have become pivotal questions in organisational development (e.g. Argyris & Schön, 1996; Nonaka, 1994). The ability to learn collaboratively with others, both within and outside of their organisation, often means the difference between success and failure. Employees, who cannot network with others to share and build knowledge, will clearly fall behind those of their peers with such abilities.

This study is part of the larger project which aims to enhance cross-cultural collaborative learning through a university course in the workplace (Slotte & Tynjälä, 2002). As previous studies have showed effective use of computer supported collaborative learning in workplace depends on much more than simply purchasing a state-of-the-art package (e.g., Corrie, 2001). Organisational structures and practices as well as pedagogical arrangements and solutions together form a framework which much determines the success of any learning program. In the present study, we are interested in how experts in human resource development (HRD) view the prerequisites for successful communications in a large multinational company. As HRD practitioners work as key professional in organisational development (see, Slotte, Tynjälä & Hytönen, 2002), their views can provide important starting points for developing elearning programs to enhance professional and organisational development.

Communication and Collaborative Learning at Work

Collaborative learning is the process of generation of new knowledge and the capability that emerges when two or more individuals explore the target information together and produce shared outcomes (e.g. Dillenbourg, 1999; Roschelle & Teasley, 1995; Urdan & Weggen, 2000). Collaborative learning requires that the participants are open-minded, tolerant and make their thinking processes transparent. Sharing workplace experiences in a non-competitive spirit may benefit the individual and the organisation.

Building knowledge together with others may lead at its best to the accomplishment of something more than could be achieved by the individual alone. Bryans et al. (1998) have stated that persons who adopt a collaborative mindset maintain an active awareness of the collaborative learning potential in every work-based transaction. Thus, making collaborative learning and career development available to people at work may offer direct benefits to employees, making learning an integral part of the enterprise.

Co-operation between universities and working life organisations has extended rapidly during the last few years (see, e.g. Bryans et al., 1998; Otala, 1998; Slotte & Tynjälä, 2002; Tynjälä, Välimaa & Sarja, 2002). Whilst university courses provide new tools for continuous professional development for fulltime employees, the completion of a long-lasting course can be a daunting task in itself. In addition to the familiar problem of finding time to study, the courses themselves may require employees to apply collaborative learning activities they are not familiar with. In particular virtual learning programs call for awareness and readiness on the part of participants to reflect their own way of learning and working. The virtual learning environment provides a freedom that, at the same time, involves taking responsibility for one's own learning process. This is difficult if the individuals rely on mere co-operation based on dividing the task in question into subtasks using a fixed division of labour and on transmitting existing knowledge from peer to peer. Although this kind of information-sharing in groups and teams is also helpful, it tends to maintain the status quo and signals acquiescence with the power hierarchy in order to avoid "rocking the boat" (Corrie, 2000).

Collaboration, instead, aims at producing a joint outcome and thus requires sharing and generating new knowledge with peers. In this way it provides better opportunities to individuals to use high-order thinking skills and problem-solving in the construction of their ideas about practice (Jonassen, 2000). Collaborative learning is based on a simple but powerful idea: to create groups or learning communities that ground their development on mutual learning processes. It requires that participants are positively interdependent to socially shared knowledge, e.g., the members of a group are selected so that they need each other in order to accomplish their joint task. This, in many cases, calls for acquiring new learning skills. The need to develop learning skills is of especial relevance for employees whose memories of formal education date back several years or even decades. The key notions here are being active and developing initiative.

Aim of the Study

In the present study, attention was not paid to how participants learn collaboratively but to how they describe the corporate communication and collaboration processes, i.e., what they think are the prerequisites and challenges for successful communication and collaborative learning in a large multinational company. In more detail, the following research question was addressed: How do HRD practitioners describe communication and collaborative learning in a large multinational company?

Study Design

Material for answering our research question was gathered from a web-based adult education course arranged for HRD practitioners working in a large multinational company. Altogether 17 participants (14 female and 3 male) from Finland and from China volunteered for the course. The course was given by the University of Jyväskylä, Finland. It consisted of all the content areas generally included in the degree program of adult education (15 credits) but was modified to support the HRD in a global company (see, Slotte & Tynjälä 2002).

A special emphasis in the course was in understanding the complicated relations between learning, communication and development in workplace. For this reason, many of the web-based discussions as part of the course were focussed on the questions of communicating and collaborating at work. We used these web discussions as a material for our study. At the end of the course this formed a database of 159 pages (Word document with single line spacing). In addition, three group interviews were carried out in China to complement the results.

All of the participants'comments were analysed qualitatively to obtain the major themes that characterise communication and collaborative activities in HRD practitioners' view. For this purpose, the principles of the phenomenographic analysis (Marton 1988) were applied.

Results

The analyses of the web-based conversations showed that HRD practitioners dealt with a great variety of different themes concerning communication and collaborative learning in workplace. In general, all participants emphasised the importance of collaboration at work and "the tremendous potential that lies within people". This was also explicated in some comments such as the following: "if we just study by ourselves and never test our thoughts with others, many good things will never come up".

As a result of the phenomenographic analysis, the themes discussed by HRD practitioners could be classified into three basic categories: (1) prerequisites for corporate collaborative activities, (2) cultural differences and (3) the role of management. In the following sections we will describe the contents of these categories in more detail. We will start with the first theme, within which, five different categories of description could be further identified.

Prerequisites for Corporate Collaborative Activities

Five categories of description for the prerequisites for corporate collaborative activities include:

(1) Individual responsibility
(2) Social skills
(3) Technical tools to support human interaction
(4) Atmosphere; open and constructive communication
(5) Adaptation to continuous change

The first category includes comments related to core of collaboration, that is building the knowledge together, emphasis being at individuals responsibility to add value to the communication process:

> Of course, we as part of the organizational network need to add value to the information and communication processes. It's not enough to store information somewhere in the Intranet or on various databases, if we do not filter and process them in a way that makes them valuable for those who need to retrieve this information. In the end, our organization is great in storing information. However, this information is usually hard to find and / or digest for those who need it.
>
> Besides, we are not only part of the network as such – we are also responsible to form, build and continuously re-build this network as to meet changing needs. Usually, elements are connected in a certain way. But in our environment, we need to make sure that the communication channels, the 'who-provides-what-to-whom' are always up-to-date.

In addition to the importance of collaboration, the course participants broadly discussed about the social skills and individual preferences of interaction taking place in connection with everyday work activities. These descriptions stressed the modest level of awareness and willingness to actively improve communication skills.

> The fact is that everyone is an expert in some area, the competence and knowledge each of us has, could help someone else if shared it with people. But the fact is that we often aren't aware of our own expertise until we start conversing with people, and through conversation find out what I could give to my colleagues and what I in return could get from them. This process of collaborative learning is in fact a joint effort to share and refine information, knowledge, opinions and ideas for mutual and organisational benefit. It is almost obvious that the prerequisite for this kind of collaborative knowledge creation

> among colleagues and superiors will be based on trust, mutual respect, and open and supportive communication, which is a two-way dialogue.
>
> In our organization that is technically very strong, the soft side of skills are often neglected or underestimated. It is not yet fully understood how important good relationships are for good organizational functioning and performance, and in the long run for the overall success of the company.
>
> I strongly agree that in our organization we should use collaboration more and encourage people to share their ideas and experiences. However, most often people are accusing that there is no time to talk with each other's, or they don't think what could be the best way to do it.
>
> When using collaboration as a method we should also remember that not everyone likes to discuss and share his or her ideas with each other's. Extraverted persons may be the noisiest ones and willing to share their thoughts as soon as possible. Introverts meanwhile need time to reflect and then maybe speak up.

Closely related to the topic of individual preferences comes the question of technical tools and the appropriate methods to support human interaction. Face-to-face communication was generally expressed to be the most rewarding method. Slightly more participants preferred face-to-face contacts to online communication although the benefits of technical tools around them were commonly acknowledged. Their usefulness was seen as "facilitating and making communication easier and faster" The following examples illustrate the opinions of the suitability of various communication tools:

> We often forget interaction between people and just send emails and at the same time we loose something very human - joy of learning together. You Nina mentioned that we should create the environment where people are participating more and they should build together something new. Do you think that it is possible only via emails? I do not think so.
>
> We needn't go to classrooms, separate courses or any other special place to learn, if we were able to see the learning opportunities around us every day.
>
> What comes to interaction it shouldn't go through paper, neither through computer, but face to face communication. I think we still have space for improvement in this area. Quite often email or the Internet are very good ways for communication, but it is not very good if we are too much depend on them. Sometimes we are just sending an email, shooting the ball in the air and wait for someone to take it.
>
> In a way this kind of online communication here in writing requires to interpret others in the way they have intended the meaning to be interpreted. In this kind of discussions, and in fact in all kind of communication, feedback is crucial, otherwise one wouldn't know how one's messages and thoughts have been understood and interpreted.

How people co-operate with each other's and create the common ground to share mutual understanding, beliefs and pre-suppositions is further challenged by continuous change. In these cases, the participants often mentioned that "change" is not really change unless it has been adopted by all the employees in the organization. Further, the participants mentioned constructive atmosphere and openness as being the most important issue to adapt to changing needs in global business. The following comments exemplify the descriptions of both categories:

> The concept of perceptual change has been mentioned several times. But what may be difficult, is how to live with it, and adopt to all those novel situations and ways of working so rapidly and constantly. I think in the process of change, constructive, open and honest communication and sharing of thoughts and concerns may facilitate the adapting process and make it easier.
>
> The everlasting change of things and organizations is a valid comment. It is not enough to learn to communicate to certain group of people. You have to learn to be able to

communicate to target group that is always changing and might have different kinds of background, opinions etc.

The nature of information we process and distribute is subject to continuous change. Only if the structure of the network and the speed fully support the business, will we be able to become a learning organization.

Cultural differences in corporate collaboration

Cross-cultural university course resulted in a large number of comments concerning the cultural differences in corporate communication and collaborative learning. The participants generally agreed that all collaborative actions are context-specific and they can be understood properly only by understanding the situation where they have been uttered. Therefore, "if a piece of communication is extracted from its original context, and expressed in another social context, it is most likely to be misunderstood and misinterpreted." These kinds of misunderstandings in human interaction were described to be rather common, especially when people from different cultural backgrounds were involved. This was partly because of "more often than not we tend to take comprehension for granted, without taking the other person's background, level of knowledge and experience into account".

> Communication is often claimed to be very ambiguous, maybe because meanings are not in words, but in people. People have different social and cultural backgrounds, education, worldviews, beliefs, norms, and attitudes against which they try and interpret other person's meanings, which again have been formulated against his/her own sociocultural background. It is a universal fact that these backgrounds seldom match. This is one of the facts that makes communication complex, and puts extra demands on the act of communication, and on how things should be said, and meanings negotiated.
> We should remember to take into account cultural differences. For example in China it is unheard of people to speak openly in front of their senior managers.

When the participants discussed about cultural differences they described it for the most part from the corporate communication point of view. In most cases, the descriptions derived from what people had been taught. These notions reflect the challenges for collaboration, which are primarily based on their previous experiences about who to talk with and how much it is appropriate to talk in certain situations:

> In the Chinese hierarchy environment, communication used to and sometimes still is perceived as top down, one-way approach. Even in the freer company context, not everyone is aware that they are supposed to respond; they are expected to explain their ideas assertively and are entitled to say no. We call it a "dead box", which means, after information goes into it, nothing is produced and it vanishes. With the discouragement, the information provider can become silent very easily, and eventually nobody takes the initiative to share.
>
> I see cultural differences here, because Finnish people are not taught to boast with something they know. And unfortunately it might sometimes be taken like that if you start telling about your experiences with an issue or telling another person how to do things. You just keep it to yourself and that's it.
>
> One point that Ann made is very important: the Chinese education and social systems do not encourage young people to criticize people of authority, i.e. parents, teachers, bosses, etc.
>
> Marianne, I also see the cultural difference HERE in China. Chinese are taught to play low on oneself on the one hand, which is recognized as modesty and on the other hand, knowledge and information are seen as power/advantage over others. There is a fear that if you "give" it to others, you don't have it any more. It sounds sad, isn't it? However, if we consider the huge population and notice the resources per capita, it gives no surprise. The scarcity of resources defines the Scarcity Mentality.

The role of management

Managers' way of confronting others openly and directly was described as the key for constructive communication culture:

> I think that managers are in a crucial position in creating and inspiring an encouraging communication culture through their teams.
>
> Where we have to become much stronger though is in changing the corporate culture. No training course can replace the motivation by the boss or other peers. We talk about intrinsic motivation as being crucial for the learning. But this also comes from the possibility to exchange and pair up with others. If the culture were an employee needs to teach others or at least summarize the most important learning points, if the boss really cared for the changes planned – then, a training course would be a big thing, a step into developing a learning organization.
>
> In the future I'd like to see the concept of collaborative learning in the form of conversation to spread also to the management level. Top management have a lot of valuable information to share, which would benefit the lower levels of management, and speed up the circulation of information and special know-how. They could act as guest speakers or facilitators in multiple occasions of learning, whether face-to-face or online. In fact, I think that this concept could be easily applied to our everyday lives if we only feel receptive for it, because in our immediate environment there is so much new to discover.

When the participants discussed about the managerial experiences, they usually criticized managers' willingness to improve their communication and other soft skills. This was seen as significant because "there are so much knowledge of effective collaborative learning that has not yet been applied into practice".

> I agree with you that practice isn't up to theory yet, and a lot needs to be done, especially in the area of management skills. Even if the management styles have changed for better direction, and 'regular' people get more and more responsibility, I still think that it is managers who with their own behavior and communication styles set the pattern for the whole team.
>
> People still tend to look for their superiors as role models. But as you said, very many managers don't seem to understand the benefit this would do to the performance and success of their teams, and that way to the whole company.
>
> It is strange that we talk about the improvement of communication and open, trusting atmosphere, but they still seem to stay on the level of words only. Often I think when participating in a course that deals with interpersonal, team building and communication skills, that more managers should participate, but they never do.

Discussion and conclusions

Three main themes emerged from the analysis of the HRD practitioner' e-learning discussions about collaboration and communication at work. First, the practitioners dealt with the general prerequisites for true collaboration and functional communication. Second, they raised the question of cultural differences that are present in the multinational workplace, and, third, they emphasised the role of management in creating the context and atmosphere for collaborative activities.

Given that the participants of the e-learning course were experienced practitioners in corporate human resource development activities, those three themes can be seen as a reflection of actual communication cultures of the company, and of the needs for developing possibilities for collaborative learning. Consequently, they can also be seen as a data which provides important hints for developing e-learning solutions to enhance communication and collaborative learning at multinational companies. In the following passages we briefly suggest some aspects to be taken account while e-learning is applied for corporate training.

As prerequisites for corporate collaborative activities the participants mentioned not only technical tools but also individual and social characteristics such as individual responsibility, social skills, adaptation to continuous change and open communication atmosphere. These are factors that cannot be taken for granted in collaborative e-learning courses. For example, supporting atmosphere has to be constructed in mutual understanding between co-workers and co-participants. In an ideal case, a face-to-face meeting before starting e-communication could provide a context for building such an atmosphere. If face-to-face meeting is not possible, the informal introduction of people and negotiation of "the rules of the game" is important. Individual responsibility grows in an environment that positively emphasises mutual dependence.

Creating a learning environment that really supports communication and collaboration at work is not an easy job. It requires strong pedagogical insight, and eye for social situations and skills of guiding others. In this respect, the role of tutors of e-learning course is pivotal. Without skilful and experienced tutors e-learning situations may not reach the level on which significant learning experiences may take place.

In addition to creating a proper context for e-learning, taking account cultural differences between participants is important. This is a question that concerns not only multinational corporations but also other large companies. The ways of communication differ between countries and ethnical and social groups. How this can be taken into account in a way that respects all parties is a different question. Maybe becoming to know different cultural practices could be an important content and aim for multinational e-learning courses. We believe that current e-learning solutions provide excellent tools for increasing intercultural awareness and respect – given that the courses are run by teachers and tutors who themselves are familiar with different cultures and cultural practices.

The role of management in collaborative corporate learning and communication was the third main theme that was discussed by our subjects. The discussions reflected a concern about the distance between the ideal of organisational development and the actual managerial practices. We suggest that in corporate training programmes – conducted either in traditional forms of as e-learning solutions – the participation of the managerial level personnel would be of fundamental importance. If e-learning courses are designed for promoting professional and organisational development it requires the participation of the whole organisation.

In sum, for the development of successful e-leaning courses for professional and organisational development we emphasise the importance of the following four principles: 1) creating open communication atmosphere, 2) use of skilful and experienced tutors, 3) arranging cross-cultural training, and 4) involving the whole organisation, including management, in professional development programmes.

E-feedback to reflect legitimate peripheral participation;
towards a redefinition of feedback in online learning environments

Abstract

Design of feedback in an online workshop is considered from the perspective of legitimate peripheral participation. A tool for gathering and reporting feedback in an online workshop has evolved and been tested in the context of ongoing practice. Social and software design issues are considered together.

Introduction

Theories of learning can be classified according to whether the underlying metaphor is one of acquisition or of participation (Sfard, 1998). With the introduction of concepts like social construction of knowledge and legitimate peripheral participation (Lave and Wenger, 1991), the participation metaphor has gained legitimacy and richness, suggesting new approaches to the design of e-learning. This paper discusses feedback as an element of design in an e-learning workshop and presents a tool to organize and focus feedback about participation. The design includes social and software components, which have evolved together and are considered together.

The use of the Internet for educational purposes is often assumed to support an acquisition perspective on learning (Brown & Duguid, 2000). But computer-mediated communication (CMC) technologies such as chat rooms, instant messages and others afford entirely new ways of participating in conversations, social networks and communities. Salmon (2000) shows how the development of the competence that participants and e-moderators need (in both technical and social aspects of CMC) is a significant learning task in and of itself. Her model of teaching and learning online through CMC includes both acquisition and participation. An individual's increasing "amount of interactivity," as suggested by the model, moves from early stages ("access and motivation" and "online socialization") to the later stages ("knowledge construction", and "development"). This suggests an increase both in the amount and a shift in the kind of participation toward meaning-making. The design of an online workshop about communities of practice must focus on that shift–by making it visible and making it a subject for extended reflection.

The problem: feedback and online learning from different learning perspectives

In connection with learning, feedback is most often an attempt to assess the performance of a ***teaching*** process: it's the transmission of evaluative or corrective information about an action, event or process to the originating or controlling actor (Wing, 1990) and it's not the learner who is in control. The most common kind of feedback in an acquisition-oriented learning situation is given by the teacher as an assessment of the student, stating whether the material that has been presented has been properly or completely acquired. The notion of legitimate peripheral participation (Lave and Wenger, 1991) suggests that a learner's position as he or she moves toward an emerging center of a community of practice is a reflection of competence. "Position" and "center" are visible to learners in a myriad of social cues. Movement towards the center involves an evolving sense of identity: this is a more complex assessment process than whether acquisition has been completed properly.

Legitimate peripheral participation in online settings is no different than in face-to-face settings, although online communities of practice may form more slowly, some of the social cues may be harder to detect, and the expression of identity may take different forms. But these differences are magnified when the learning process takes place in a time-delimited episode such as a workshop. A community of practice perspective should influence the design of feedback to and from the learner as much as possible.

Online workshops designed as a community of practice suggest that feedback be reconceived from the perspective of the participant. In agreement with Putz and Arnold (2001, 194) we would argue that the design of such a workshop never completely determines the learning practices. The participants make use of the learning space offered by the workshop and co-create their learning through (constant) interactions with each other. Our design of a Community Barometer offered workshop participants opportunities to reflect on their interactions with each other, with "the content," and on their experience of the process itself.

When the subject of the workshop is "communities of practice," the importance of carefully designing the feedback increases. This project has taken an action research approach by reflecting on theoretical issues and, at the same time, reporting on the evolution of a tool that was used in just such an online workshop. The challenge has been to design a feedback tool that helps workshop participants learn–and gain insights into the general process of learning in a community setting. This implies that feedback is *"feedback to the community"* rather than to an authority figure. It's simultaneously *"feedback about the community"* and, significantly, *"feedback from the community."* Figure 1 suggests how the Community Barometer and the discussions around it can be the center of a reflective process.

This approach has further implications for software design as a support for social arrangements among workshop participants. As the design of the social process has evolved, the software to capture and represent the experience has had to evolve as well. Situating information capture and representation in the workshop space then becomes an important design problem.

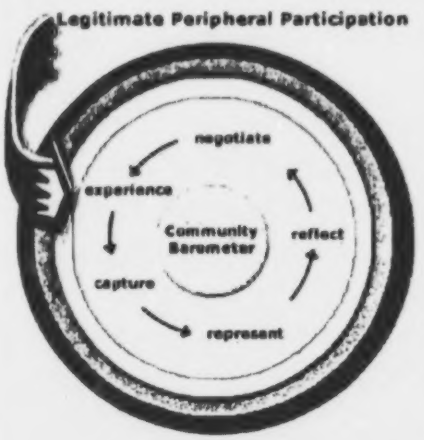

Figure 1: Conceptual model of Community Barometer use

Case description

Our feedback tool was developed in the context of an online workshop in which readings about communities of practice were discussed and in which a community of practice was simulated. Although the workshop involved teleconferences, email messages, and side conversations in various media, the main "space" where the workshop met was a customized conferencing site on a Web Crossing platform. As the design and delivery of the workshop have evolved over 4 years and 10 offerings, many elements have been introduced to help workshop participants visualize their own participation in relation to that of others. These examples of visible participation are illustrative:

- The foundation for the workshop was the online conversation over the course of five weeks. It offered several different kinds of conversations, playful and formal, all designed to encourage participation and reflection on participation. These different spaces are in effect "a curriculum," representing different facets of a community's life. Each offers a different kind of interaction and embeds different feedback characteristics.

BEST COPY AVAILABLE

- A "Community Directory" supports "back-channel" participation by providing each participant's name, thumbnail photograph and contact information such as telephone number, organization, and email address. In addition, it calculated a participant's local time and length of time since last login.
- The customized workshop platform provided a readily available instant messaging facility and a way to see who is "present" on the website. The list of people who are present linked to an instant message tool, which provided a much-used resource for chit-chat and feedback of various sorts.
- Workshop participants were asked to take on specific leadership tasks and roles that supported the activities and learning of the workshop community. These tasks were a version of stewardship roles described in Wenger (2000). Participants read brief descriptions of what these "leadership tasks" entailed, signed up for them at the beginning of the workshop, and then were coached by one of the facilitators as they carried out their duties. Each of the tasks involved reflection on community needs, trajectory, and general attitude. Participants signed up for leadership tasks as teams–with other members of small groups to which they were assigned at the beginning of the workshop.

There were many other ways in which both the design and production of this workshop emphasized participation and social learning processes. Feedback was woven into the design and production on many different levels. It began with the first contact before the participant had actually registered and continued through follow-up contacts after the end of the workshop.

Method

This paper uses an action research framework, since the authors were participants in the workshop, playing several different roles at different points in time (Baskerville, 1999). In this stage of the research Grounded Theory coding has not been used. Each iteration of the research process consists of five phases: diagnosis, action planning, action taking, evaluation and specific learning. Although work in this area began earlier, this paper focuses on the workshop offerings in Fall 2001, Winter and Spring of 2002.

Design issues: the software and the social system

The main issues regarding the design of feedback in this workshop are:

- The workshop was quite short (5 weeks) and the learning curve was rather steep in the sense that many participants were struggling to understand the readings that were being discussed as they were confronting a complex CMC environment for the first time.
- Voluntary participation served as a test of relevance. Most participants in the workshop had full-time jobs and had underestimated the amount of time that participation in an online workshop entailed. The voluntary aspect of discussions and tasks were as important in this workshop as they would be in any community of practice: attention acted as a built-in relevancy test and was an element of community rigor. Attention, therefore, is a fundamental kind of feedback.
- The workshop was co-produced with the participants. Workshop participants were asked to carry out tasks that illustrated community leadership roles that normally emerge over much longer periods of time (Wenger, 2000). Some of these roles (such as organizing and facilitating teleconferences) were relatively intuitive and familiar to the participants. Others (such as some of the reflective tasks) seemed more difficult for participants to conceptualize and execute. There was a natural tension between allowing participants to shape their own roles and insuring that the work of the simulated community actually got done. The very notion of a community of practice

suggests that too much facilitation (or facilitation that is too directive) can undermine the self-organizing capacity, even of a simulated community such as this workshop.

- Although the workshop was artificial in some ways, the relationships and the learning that occurred during the workshop were real. Participants were invited to reflect on the process of community formation and the related learning issues.

All of these design issues served as a kind of diagnosis: the feedback process needed to be somewhat formalized, the process needed to engage the attention of workshop participants voluntarily, and their attention needed to be drawn to issues at a community level. The focus of the feedback needed to be on the community development process, but the feedback process itself could not be too directive or depend too much on the intervention of the workshop leaders.

Design process

The online questionnaire that has developed addressed the foregoing issues and was used in the Fall 2001, Winter 2002 and Spring 2002 workshops. The process of design evolution is expected to continue.

Originally the Community Barometer was conceived from a spatial perspective (Coenders 2002). The questions were suggested by a spatial metaphor whose logic was roughly: an online "space" accommodates activity, interaction and insights that enable learning. The "amount" of space and the functioning of the space may have a significant effect on enabling a workshop's outcomes. Space in this view is a mix of virtual, mental and interpersonal space and is compatible wth the concept of "Ba" as introduced by Nonaka. This led to a survey that combined closed-form questions and open-ended responses. It was used experimentally as a participant mini-project in the Spring 2001 workshop and subsequently evolved into the Community Barometer.

As a result of the first trial, the questions were re-organized, the questionnaire was automated and the administration of the questionnaire was incorporated into the Fall 2001 workshop. The questions which had been developed independently were found to fall nicely into the model that Wenger (1998) had developed for a community of practice. The Web Crossing platform provided good facilities for storing information such as questionnaire responses in the user record and its programming languages enabled the automatic aggregation and reporting of stored data. Through a connection between the Community Barometer questionnaire and a discussion titled "Reflecting on our experience," workshop participants were brought indirectly into the feedback design process.

Implementation

The Community Barometer questionnaire added two forms of feedback to the discussion: closed-form responses and open-ended questions. The closed form component asked participants to rate the extent to which they experienced the workshop community as:

Domain	1. Discussing the right topics
	2. Sharing perspectives and ways of thinking
	3. Finding new concepts and frameworks
Community	4. Being together with each other
	5. Developing enough trust for deep discussion
	6. Building collaborative relationships
Practice	7. Participating in setting direction and tone
	8. Evolving communication practices along the way
	9. Working towards useful outcomes

The open-ended response component of the questionnaire asked respondents to give a brief example to illustrate their experience of the closed-form question. A screen-shot of the questionnaire is shown in Figure 2. Workshop participants could change their responses at any time during a week. Notice that the Community Barometer questionnaire page, like all others in the workshop, had a navigation bar along the left which provided access to several different resources, including the Barometer questionnaire and the Barometer results summary page. The bar chart in the lower left hand corner of Figure 2 represented the median and quartiles of one question and was a link to that section of the Barometer results summary report. Which question was represented, as well as where in the summary report the link takes you, depends on the location in the workshop. For example the Domain questions pictured in Figure 2 were associated with formal discussion spaces in the workshop while questions associated with the concept of community were associate d more informal and playful spaces.

Interim Workshop Experience – Week 5

Domain

1. Discussing the right topic: Raters: 14 , Average: 4.0

Hi:

Md:

Lo:

3: Given the wide range of topics under discussion, it's difficult to know what's "right".

3: The questions were interesting but didn't generate much discussion. Was that the questions? or people's involvement elsewhere?

3: In general the right topics are brought, but I just could not take whole advantage of them Probabaly too many at the same time, diverts the attention, specially when you are short of time

3: We're discussing too many things (the right things, probably, but too many to get deep discussion)

4:

4:

4: I feel the topics being discussed are pertinent to the workshop and useful to the participants. They are very useful to me at this time.

4:

4: I think we're very much on track although so many new topics are being introduced.

Fig 3: Community Barometer results summary page

BEST COPY AVAILABLE

All workshop participants were able to see an anonymized summary report of all responses at any point. As shown in Figure 3, the summary report grouped the open-ended comments by the corresponding closed-form score. Therefore, for each of the nine questions, the open-ended responses at a given point on the scale from one to five were shown together. Since the questionnaire and the results summary changed each week, the responses and the summaries pertained to a specific week. During the course of the workshop, the summary reports from the preceding weeks were available, permitting comparisons from one week to another. The responses illustrated in Figure 3 represent the lower end of a symmetrical distribution that ranges from 3 ("neutral opinion on whether the right topic is being discussed") to 5 ("strongly agree").

There were two ways in which the Community Barometer was woven into the social fabric of the workshop community. The first was to tie it closely to an ongoing discussion titled "Reflecting on our experience." The navigation bar on every page in the workshop website linked directly to both the Barometer questionnaire and to the summary report. These in turn linked directly to the "Reflecting on our experience" discussion. Although many discussions in the workshop were time-bound (e.g., the "Welcome to the workshop" discussion was only active at the very beginning), "Reflecting on our experience" was an ongoing discussion that went on for the duration of the entire workshop.

The second way was to have the leadership team facilitate the "Reflecting on our experience" discussion. This team explicitly signed up to consider the development of the sense of community, to encourage participation in the reflection process, and to interpret the Barometer summary report. The team facilitating the community-wide discussion typically held small-group discussions in their own personal space about the facilitation task, about the Community Barometer, or about the reflective process in general. The team's personal space was open to others but was infrequently visited by people not on the Barometer team.

Feedback produced

The following feedback was produced by the Community Barometer:

- The number of responses, the average, median, upper- and lower-quartiles were calculated and provided in appropriate locations, shown as numbers and represented graphically. (See Figures 2 and 3.)
- Each participant could see how his or her scores compared to the group statistics.
- The comments of each participant on each question were shown anonymously in the Barometer summary report.
- Each participant could see how his or her comments compared to those of others.
- Cumulative data was not automatically displayed but was made available to the Barometer facilitation team, which, in some workshops, published week-to-week comparisons.

Outcomes & observations

The Community Barometer was used in three workshops, during the Fall of 2001, the Winter of 2002, and the Spring of 2002. The following observations were made during these workshops:

- Most workshop participants completed the questionnaire and many offered rich and insightful comments about their perceptions of and reactions to the workshop experience. The percentage of workshop participants completing the questionnaire declined over the course of each workshop. Less than half of the completed questionnaires contained open text "examples."

- Support and guidance for the leadership team that volunteered to work with the Community Barometer turned out to be crucial. Just as the software implementing the Barometer questionnaire and summary report evolved through experimentation, the instructions to the leadership team evolved as the meaning of the task was negotiated, as different team members offered new skills and perspectives, and as the workshop leaders gained experience in the process. For example, because of the amount of work entailed by this leadership task in the Fall of 2001, three different teams were recruited in the Spring of 2002, one team for each of the active weeks. The effort involved in understanding the task and stepping into the leadership role was such that in the Spring of 2002 we reverted to the simpler but more onerous design where one team took on the task for the duration of the workshop.
- Messages from the leadership team inviting participants to complete the Community Barometer or to join the discussion "Reflecting on our experience" were effective and fit into the self-organizing spirit of the workshop.
- Although the Community Barometer summary did come up in the discussions on "Reflecting on our experience", it was not necessarily the center of the discussion: the Community Barometer could be ignored as such even though the discussion (about, for example, the appropriate length of postings) touched on issues that were also mentioned in the Community Barometer summary report.
- Workshop facilitators referred to the Community Barometer summary report and found that it reflected events, concerns and emerging topics. Although it did not provide easy answers, obvious "fixes" or suggest course corrections, it was a useful resource.
- The comments in the Community Barometer and in the discussion "Reflecting on our experience" were fairly divergent. Careful attention and skill on the part of the leadership team was needed to keep the discussions focused and productive.

Conclusions and discussion of what we've learned

The reflection which we have encouraged in the workshop is an unpredictable process in the sense that it is multi-layered, is only partly visible and it interacts with all of the other online activities. The same can be said for the process of writing this paper. Here are several issues that rise to the surface in reflection on the development process as a whole.

- The Community Barometer should be regarded as a social "affordance" (Norman, 1988 and Norman 1993) in the workshop community's life. The way it appears to the community suggests meaningful improvisation and additional uses. Its actual use is a combination of many factors, ranging from its mechanical design, its wording, its placement and availability, the leadership of a team of volunteers and the coaching they receive. The community's response is quite complex and changes over time.
- It is worth speculating whether synoptic community awareness is too lofty a goal for a barometer in a fast-paced online workshop; a more modest goal that a tool (and associated practices) might aim for is something like proprioception, in the sense that different actors in a community sense the amount of "stretch" or effort that's appropriate for their function.
- Designing feedback for an emergent entity–a community that doesn't exist at the beginning of the workshop, but which is in the process of forming–involves some subtle paradoxes. Distinguishing between assumptions, intuitions, and evidence in a fast-paced online environment is a challenge both for workshop leaders, the designers, as well as the participants.
- The temptation to assess the assessment tool with a questionnaire was strong. Resisting the temptation seems, in retrospect, to be very much in the spirit of learning

suggested by Lave and Wenger (1991) and Wenger (1998). Ongoing reflection and discussion by the participants in a workshop seems to be a productive strategy for the development and assessment of a tool. That belief has general implications for the development of software tools.

- Using the barometer questions, software, and practices in other settings would nevertheless be productive.

Just as a common barometer indicates a possible change in weather conditions, the Community Barometer described in this paper provides evidence of community conditions–that community members must interpret with care. It captures and presents subjective experiences and as such supports an intersubjective reflection and negotiation process. As weather fluctuates within a dynamic range of equilibria, a community fluctuates along three dimensions: community, practice and domain. The Community Barometer aims to indicate some fluctuations so people are alerted to areas and issues that deserve attention. The Community Barometer is a way to prepare participants for the sunny and rainy days of community life!

Exploring Opportunities for Online Instruction for Individuals with Severe Disabilities

Nathan M. Sparks
Virginia Alternate Assessment Program
Division of Assessment and Reporting
Virginia Department of Education
United States
natesparks@excite.com

Abstract: This article examines the current state of available programming and content delivered via the Internet for individuals with severe disabilities. An examination of current research points to a lack of free programming and content devoted to the educational needs of these students. Currently available resources for individuals with more significant disabilities are limited by many factors including costs for training and materials, lack of accessible web-sites for individuals with significant disabilities, relevant programming and information, lack of free programs, understanding the interrelationship between student learning needs and instructional delivery systems, and the ability for developers to address the programming needs of this small population of end-users. Programming for this population should focus on functional academic support, daily living skills instruction, job exploration, and online recreational opportunities. Access to programming should provide multiple points for end-users and provide content in varied formats to suit individual needs. It seems the challenge of using the Internet for instruction of students with severe disabilities may require educators to examine a new paradigm of instructional delivery.

Foundations

"As technology becomes more advanced and technologies are merged, it becomes more important that technology and learning relationships are thoroughly explored and understood. Until these relationships are better understood, there is a good chance that technology will continue to have much less impact on special education than we all believe is possible" (Hasselbring, 2001).

The Internet has had a profound affect on instructional programming for many student populations. The purpose of this article is to examine the feasibility of providing online course materials and support for students with more significant disabilities. For purposes of this discussion, this article will consider the definition of mental retardation and severe disabilities as specified in the Individuals with Disabilities Education Act, 1997. "Mental retardation means significantly sub-average general intellectual functioning existing concurrently with deficits in adaptive behavior and manifested during the developmental period, that adversely affects a child's educational performance" (IDEA, 1997). Individuals typically considered as having significant (severe and profound disabilities) will usually demonstrate IQ levels below 40 and may also have additional disabilities, including movement difficulties, sensory losses and/or multiple disabilities which may foster behavior problems. This article will examine existing technologies for Internet access and the specific programming needs of individuals with significant disabilities.

The practice of using the Internet as a delivery system for educational programming has flourished in the past decade. Entering "online course" in a web search engine will generate upwards of 263,000 entries (www.alltheweb.com search results, April, 2002). Most major universities across the globe have developed and provide some form of online instruction to offer class content, support or information. Likewise, the public school environment has begun to develop and implement online course content for students at all levels. With continued improvements occurring in technologies associated with the Internet, these trends are likely to continue (Hofstetter, 2001). Currently available technologies for computer access exist for students with significant disabilities, however programming and content on the World Wide Web (WWW) is limited to purchasing programs from selected vendors and web-sites that are sometimes

BEST COPY AVAILABLE

inaccessible to this population. The Internet can be used as a resource and instructional tool for these students, however content and accessibility must be addressed in the design of web-sites and programs for this population (Hasselbring, 2001).

Available Technology

Internet technology has revolutionized instructional delivery systems for many populations. However, many localities may have a difficult time finding funding and resources to provide Internet access for students. Therefore, "very little hard evidence is available showing what learning gains might be expected from infusion of high technology, in part because there are very few classroom situations where an entire class has ready access to technology throughout the school day" (Tiene & Luft, 2001). This points to one of the serious challenges facing implementation of Internet instructional systems; the ability to provide computer technology, training and related equipment for students and teachers. This becomes even more difficult as it relates to special education and the needs of individuals with significant disabilities. Most students falling into this category of disability will need hardware designed to offer them access to the Internet (Snell & Brown, 2000). This could include switch technology, alternate keyboards, voice recognition software or hardware, and interface programming and hardware to allow functionality. All of these technologies are costly, and in some instances, hard to locate. Findings from the 2001 Report on Special Education Programs in California point out that "technology and equipment for instruction and mobility of students with perceptual and/or motor disabilities is not available or very outdated" (CDE, 2001). Dr. Fred Hofstetter sums up the current situation as follows, "In theory, the ubiquity of the Internet provides the opportunity for teachers and students to remain in touch virtually when they cannot interact personally in the classroom. In practice, educators need software that enables them to put courses online, view student performance data, identify problems when students encounter difficulty, and provide scaffolding to help students overcome the difficulties" (Hofstetter, 2001).

Even with all of the difficulty surrounding accessing the Internet for instructional purposes, most teachers, parents, and students view the Internet as a viable instruction tool. When questioned about Internet educational delivery practices in a study conducted by Lewis, Harrison, Lynch and Saba, teachers and administrators stated that technology use improves academic performance, increases student on-task time, provides quicker access to information and learning, and exposes students to new "types" of learning (Lewis et al., 1994). We can conclude from this study that teachers and administrators see online educational structures as positive learning systems. Unfortunately, these systems may be costly to divisions in meeting training and equipment needs (CDE, 2001). "The many years of under funding and the inequitable distribution of what funds were available, has resulted in some districts capable to provide while their neighbors struggled to meet minimal standards" (CDE, 2001).

Internet technologies have made access to instructional materials and content easier for those populations able to access the World Wide Web. Further, access to the web provides students with multiple occasions to interact with a broad range of learning opportunities and environments (NCIP, 2001). Access to the web may be in the form or programming or hardware, but systems must be designed to address the specific needs of varied users with disabilities (Tinker, 2001). This access needs to be expanded to include students with more significant disabilities. In order to provide this access, systems to address the needs of these students should make use of available technologies and access systems to minimize expense and training demands for potential end-users.

Providing Programming for Students with Severe Disabilities

There are many challenges and rewards to be found in providing programming and instruction to students with severe disabilities via the Internet. There are many characteristics of typical individuals with severe disabilities (Snell & Brown, 2000) that are well-supported and enhanced via Internet technologies and computer instruction delivery systems. Independent learning, self-paced access, variable levels of support, and repeated practice are important factors identified as effective instruction for individuals with significant disabilities (Snell & Brown, 2000).

The format of instructional delivery lends itself to independent interaction and learning, which has been a cornerstone in the individualized programs used by these students. When teachers use the Internet with these students, the role of the teacher is altered and the computer becomes the instructor, which fosters student-driven discovery and learning (Sprague & Dede, 1999). Students are allowed to access the information at their own speed and control repetition of content.

Students with more severe disabilities are often using picture communication systems as their mode of communication (Downing, 2002). Internet technologies have made images readily available over the WWW. Using pictures can make curriculum more accessible for students with significant disabilities. "They are able to use visual clues without struggling with text" (McInerney, 2000). This is an example of how Internet instructional delivery may be superior to other modes when working with certain populations of students. Images can be combined with narration to provide learning experiences that are more accessible to the student.

"Clearly, one could argue that in many cases, students with disabilities have a greater need for accessing technology than do their non-disabled peers. This may be especially true for students who need technology just to function within the school environment, such as students with sensory and physical impairments. However, even many students with high-incidence disabilities, such as learning disabilities, require technology to function in the school environment"(Hasselbring, 2001).

Instruction in leisure activities is a component of most programs for students who have severe and multiple disabilities. The Internet can provide a large array of visual and auditory content to address this area of needed instruction. Students with severe disabilities can use computer access and currently available Internet web-sites to explore leisure activities and make activity choices (Dattilo, 1986). One type of leisure instruction could be Internet field trips for students. Students can exchange information about where they live and visit locations via web-sites to experience different settings (Harris, 1994). Although this has been proven to be an effective delivery system for this population and content area, many students with severe disabilities "under-utilize assistive technologies" related to leisure activity instruction (Wehmeyer, 1999).

The Internet can provide opportunities for repeated exposure to the same content and lessons driven by student needs. Finding content that is focused towards those needs for students with significant disabilities is difficult. It is important that teachers examine the relationship between the capabilities and inherent qualities of the Internet and their specific student (Hasselbring, 2001). It is not enough to simply provide these students with access systems to "surf" the web, we need to provide them with instructional programming that is relevant to specific student needs and Internet experiences that are enriching to the student's daily life. Some of these areas of identified instructional need include functional academics. Content focusing on support of functional skills, such as purchasing foods at a grocery store, writing checks at a bank, or utilizing public transportation can be supported and instructed through visual presentations delivered via the internet. Daily living skills, such as washing hands, doing laundry, doing dishes, or using the telephone can also be adapted and instructed in various formats delivered over the internet. Job exploration can be accomplished through descriptive and visual formats that provide students with significant disabilities information about job expectations and skill requirements.

A major issue relating to available Internet content for students with severe disabilities has been the lack of free content specifically designed for access and use by these students. Content needs to be modified to provide students with significant disabilities avenues of access that are meaningful and useful to their individual educational program. This requires many individuals coming together to create content and programming focused on the student with severe disabilities. "Realizing the potential of the new educational technology for learners with special needs will require a coordinated effort that in not going to happen by itself" (Hofstetter, 2001). The main difficulty with available content for this population has been that the number of possible end-users has not been high enough to warrant site and program development. The "too narrow market" has limited commercial appeal and therefore, limited choices for this population of student (Tinker, 2001). Organizations and educational institutions need to examine funding and explore grant possibilities to provide web-sites devoted to the programming and content needs for this population of students.

A final consideration that needs to be addressed in providing content and programming for students with significant disabilities is the need for adaptable programming. Adaptable programming should provide content and programs that can be modified by end-users to fit specific access or use issues.

BEST COPY AVAILABLE

These access issues may be the need for an end-user to use a single switch, multiple switches, simplified graphic presentations, color or monochrome graphics, auditory supports or extensive auditory prompting, or visual supports that are flexible enough to allow use of the specific program without audio. All of these adaptability issues must be built into content and programs offered to this population because of the wide array of student skills and needs presented when dealing with individuals with significant disabilities.

Conclusions

The Internet can provide educational instruction to a wide variety of individuals. The qualities of Internet instructional delivery systems seem to fit well with the educational needs of students with severe disabilities. Instruction over the Internet can provide independent practice, repetition of materials, visual and auditory learning experiences, vast resources for exploring leisure activities, and student discovery learning. However, currently available resources for individuals with more significant disabilities are limited by many factors. These include costs for training and materials, lack of accessible web-sites for individuals with significant disabilities, relevant programming and information, lack of free programs, understanding the interrelationship between student learning needs and instructional delivery systems, and the ability for developers to address the programming needs of this small population of end-users. Programming must address the functional academic, daily living skill, recreation and vocational needs for this population of students, as well as the various access issues surrounding use of the Internet and computer technology. It seems the challenge of using the Internet for instruction of students with severe disabilities may require educators to examine a new paradigm of instruction. "Using technology for providing access and delivering instruction is inadequate by itself. Special educators must adopt a new model for learning to meet the challenges of the next century, and they must use technology in new ways to meet these challenges" (Hasselbring, 2001).

The Use of Electronic Portfolio's in Allied Health

Jeffrey V. Stewart, III, PhD, Macon State College,
Kenneth E. Wright, DA, The University of Alabama,
Vivian H. Wright, PhD, The University of Alabama

Introduction

Information technology permits expanded and more substantial student evaluation opportunities than is possible with traditional evaluation techniques. Additionally, technology use provides links to the educational process in ways never before possible, by helping to overcome the constraints of distance and time. In the education and training of students, educators must develop emerging tools and techniques to enhance the students' educational and professional development.

The electronic portfolio is such a tool in the professional development of students as well as being utilized as an evaluation method by faculty members. The electronic portfolio allows students an opportunity to reflect upon professional development, supply documented evidence of professional growth, and provides a unique tool for assessment throughout the academic career and clinical experiences.

Faculty members continue to search for effective ways to access students using practical outcomes. The electronic portfolio offers faculty the opportunity to focus on the learning and assessment of the students. When introduced to the concept of creating an electronic portfolio, many students ask, "What is an Electronic Portfolio?"

What is an Electronic Portfolio?

An electronic portfolio is an active learning reflective tool created by the students to assess both learning and knowledge (Cambridge, 2001). The electronic portfolio allows a student to document both academic and professional growth over a period of defined time using a digital collection of examples which are sometimes posted on a student website and sometimes saved to removable media such as a CD. The faculty member responsible for the particular student's academic development often defines the period of time, which can be as short as a one semester course or as long as an entire academic program.

Upon completion of the portfolio, the student has a practical product that can be assessed by faculty members as well as a tool that can provide evidence of a high level of learning to multiple audiences. Potential employers may use this tool as an example of a multi-skilled professional, which is highly desirable in today's workforce.

Quizzes, papers, and tests are the usual forms of assessment which many students fear (Cambridge, 2001). These measures provide a threat of poor grades, which often produces some level of incentive to study, but they do not produce encouragement for active learning. Hansen and Stephens (2000) write, "many college students today (unrealistically) judge their own academic competence to be high, and tend to blame low performance on poor instruction" (p.42). They further stated, "Schools tend to condition students to focus on products and ignore the process that leads to those product" (p.45).

The electronic portfolio allows students to focus not only on the outcome, but also on the process of creating the final product. The portfolio can not only be used as an evaluation method, but also once started; it can be continuously updated much like a more in-depth resume or curricula vita.

Framework of the Electronic Portfolio:

Once a faculty member has introduced the elements to be included in the electronic portfolio, the student may then begin to accumulate the different elements in preparation for creating the final product. Specific items that may be included in the portfolio could consist of a resume, personal information, professional presentation, example of writing, personal reflection on and evaluations of a professional experience, current research agenda, as well as many other items. The development of the electronic portfolio is a direct result of the purpose of the product and the audience for the product (Yancey, 2001).

Four characteristics adapted from Liz Hamp-Lyons and William Condon's *Assessing the Portfolio: Principles for Practice, Theory, and Research* (1998) provide the framework for the development of electronic portfolio:

- *Multiple examples of work can be featured.* Student progress can be documented through multiple examples of work over a given period of time. Students are able to produce evidence in their own progression toward increased critical thinking skills if examples throughout the process are provided.

- *Examples of work can be provided in the proper context.* Not only can an example of the students ability to write be included in the portfolio, but also included can be the actual assignment and grading rubric for the particular assignment so that the example may be seen in the proper context, not just an abstract example of the work.

- *Opportunities for self-assessment and selection are created in the electronic portfolio.* Students have the opportunity to make decision as to what will be included in the portfolio based on a selected set of criteria, the reader should be exposed to examples of the highest quality from the student. This is an important component of the portfolio, as the student must choose products that are desirable to the audience.

- *Evidence of development over time can be achieved.* Creators of the portfolio can demonstrate their learning over a period of time. This is done because the portfolio provides the opportunity to reflect on previous entries as well as continue to add work as appropriate.

No matter the model of development of the electronic portfolio, the creation of the product is a direct result of both the audience and overall purpose of the end result. Students learn to document learning and professional development that takes place in a given time.

The use of the Electronic Portfolio in Allied Heath

Many allied heath disciplines use clinical experiences as an essential component in the curriculum both on the undergraduate and the graduate level. Other ways of gaining practical skills is through the use of internship opportunities. Typically, students are employed by campus organizations for some pre-arranged period of time. One of the challenges of these types of courses is the evaluation of such an experience. Many of the internship or clinical experience coordinators are more than willing to complete mid-term and final evaluations on the candidates, which will allow assessment in such areas as commitment to the organization, willingness to work with others, but these types of evaluations do not allow the student to reflect on the experience.

An electronic portfolio gives the student the opportunity to reflect on the clinical or internship experience. They are able to document the results of the experience in many different aspects of professional development. They are able to show what their role was during their experience, which they worked with, what skills they used and improved as well discuss some issues that were discovered during the opportunity that may be important in the workforce. (Yancey, 2001, Springfield, 2001).

Electronic portfolios can also be utilized as an outcome for an entire program. The development process occurs not just during one course or term, but also over the complete academic program. Using this model, students have the ability to reflect on their academic growth over a much longer period of time using several examples of documentation. Assessment then takes place in some format such as a final presentation activity where all students completing the specific program would come together and present the electronic portfolio to a select group of faculty members. One potential application would be in addition to or in lieu of a comprehensive written exam.

Conclusions:

As technology continues to become an ever-increasing component of the academic process, where and when to utilize technology is critical to the educational mission of academic programs. The electronic portfolio is one tool that provides opportunities for documentation of learning as well as assessment. In addition, students creating an electronic portfolio can use this tool for reflection over a give period of time and to record, interpret, and evaluate his or her own learning.

The electronic portfolio has many potential uses in allied heath disciplines including an outcome for a specific course, clinical or internship opportunity or as a final project upon completion of an academic program. Once the parameters have been determine as to the purpose of the electronic portfolio and the elements to be included, the creation of the product shifts to the student to collect, select, and reflect on their accomplishments for inclusion in the electronic portfolio.

Localization vs. Internationalization: E-Learning Programs for the Aviation Industry

Judith B. Strother

Introduction

An increasing amount of research is being done on the topic of internationalization and localization of communication products. However, much of the focus is on the world of Information Technology. While that is certainly critical, especially in this era of web-based communication, the consideration of character sets supported by a particular operating system and expansion of text due to translation issues are not the only issues. In many cases, the content of the communication itself must be localized because of such elements as varying legal requirements and regulations, and linguistic elements such as dialectal variations.

E-learning programs – especially those that are designed to be delivered around the world – have their own set of issues with localization. This paper presents a case study of a web-based English language training program in the field of Aviation.

English is said to be the *lingua franca* of the world of aviation because it is supposed to be used by pilot and air traffic controllers the world over. However, the Aviation English used in Europe is not the Aviation English used in the U.S. and neither of those may be the version of English used in other parts of the world. While there are continuing attempts by international regulatory bodies to mandate the use of English and then standardize the English used in aviation throughout the world, the fact remains that differing versions are commonly used in different locales.

What effect does this have on a product whose goal is to teach a standardized version of Aviation English? How does a training program cope with the international need for standardization and the reality that localization is the only way to deliver the significant parts of product?

Case Study – the Aviation English Product

Virtual Languages, Inc., (VL) of Boca Raton, Florida, develops and delivers distance-learning courses that teach English as a Second Language (ESL) within an English for Specific Purposes (ESP) framework. This allows learners to improve their proficiency in English while developing the field-specific language they need in order to perform their jobs. The two main ESP areas of VL courses are Business English and Aviation English, the latter of which is the focus of this paper. Virtual Language's Aviation English courses are based around content-rich themes such as Introduction to Aviation, Aviation Meteorology, Aviation Physiology and Medicine, and Aviation History.

All courses are available at five proficiency levels and focus on the primary language skill areas. Each course has several sections, all based on a content-specific Reading Selection. Vocabulary development, reading comprehension practice, and grammar activities (at the lower levels) are part of each lesson. In addition, a crucial part of each lesson involves two different kinds of listening activities. One provides a variety of listening activities, based on the content of the Reading Selection. The other activities are based on actual ground-to-air communication events. At the lower levels, there are activities that prepare the learner for pilot/ATC communication using standard phraseology and at the upper levels, actual airport tower tapes are the basis for the listening activities to give the learners practice with authentic language delivered in actual context.

The listening section of the Aviation English course, based on radiotelephony phraseology, provides the greatest localization challenge for the global delivery of the web-based product. How can we decide which version of pilot/ATC communication to use: FAA? ICAO? or a real (but sometimes nonstandard) version of one or both?

Localization versus Internationalization

While various organizations use these terms differently, this paper uses the definitions adopted by LISA (Localisation Industry Standards Association), using LEIT (LISA Education Initiative Taskforce) guidelines (LISA 2002).

BEST COPY AVAILABLE

Localization involves taking a product and making it linguistically and culturally appropriate to the target locale (country/region and language) where it will be used and sold. A similar definition for localization is the process of creating or adapting a product to a specific locale, i.e., to the language, cultural context, conventions and market requirements of a specific target market (Localization Institute 2001).

Internationalization is the process of generalizing a product so that it can handle multiple languages and cultural conventions without the need to re-design. This process is particularly relevant during the program and product development phases as well as relevant to decisions made about the documentation to accompany a product. (LISA)

In addition to localization and internationalization, globalization addresses the business issues associated with taking a product global. This involves integrating localization throughout a company, after proper internationalization and product design, as well as marketing, sales, and support in the world market. LISA also uses a new acronym, GIL, to describe the combination of Globalization, Internationalization, and Localization. GIL refers to all aspects of the process of taking products to an international audience.

Localization and Internationalization are the two concepts that form the basis for this discussion since they are relevant to the development of the product, even though the product itself (Aviation English course) is only delivered in English. Other globalization issues, such as culturally translated marketing materials, are not within the purview of this paper.

The Problem

While international regulatory bodies continually attempt to standardize the English used in aviation throughout the world, different versions are commonly used in different locales. How does a web-based e-learning program cope with the international need for standardization and the reality that localization is the only way to sell (and thus deliver) the product? This complex process is discussed, including identification of the parts that could be internationalized (usable for anyone in any country) versus those that had to be localized for different world regions.

Aviation English

While English is assumed to be the international language of aviation, in fact, there is not an enforceable requirement for English to be used in all pilot-ATC communication nor is there a minimum or consistently measurable standard of English proficiency for pilots or controllers. Even where English is used as the language of communication, there is no agreement on which form of English (that is, *whose* English) is to be used as the standard.

Proficiency Issues

A great variety of cross-linguistic interactions between pilots and controllers is possible. Consider these few examples:

- both native English speakers but from different dialectal areas (e.g., a U.S. pilot flying into Australia)
- a non-native speaking pilot / a native speaking controller (e.g., a Chinese pilot flying into the U.S.)
- a native English speaking pilot / a non-native speaking controller (e.g., an Irish pilot flying into Venezuela)
- a non-native speaking pilot / a non-native speaking controller in another country, where both speak English as the common language. (e.g., a French pilot flying into Japan)

In the United States, the Federal Aviation Administration (FAA) requires flight certificate applicants to demonstrate proficiency in English, yet there are no assessment standards given to measure their concept of proficiency. Current FAA regulations require pilots to "be able to read, write, speak, and understand the English language." (FAA)

In most of the rest of the world, the International Civil Aviation Organization (ICAO) sets the standard for pilot/ATC communication. In a move to get closer to requiring English as the international language of

BEST COPY AVAILABLE

aviation, ICAO, the UN-affiliated body responsible for setting safety standards for air transport, recommends that control towers and commercial aviation use English, but it is only a recommendation and no proficiency standards have been set.

Standardization Issues

There is a significant body of evidence that confirms that miscommunication has caused numerous accidents and near misses around the world, especially miscommunication between native speakers and nonnative speakers either as pilots or in the control tower without adequate command of English.

In fact, the worst aviation disaster in history resulted from a simple communication error on March 27, 1977, in Tenerife in the Canary Islands. When the pilot of a KLM 747 started his take-off roll down a foggy runway, he radioed the tower "We are now at take-off." The controller misunderstood this ambiguous statement and incorrectly interpreted it to mean "We are at our take-off position and holding." After all, that was what the tower had instructed the KLM pilot to do. Therefore, the controller did not warn the Dutch pilot that a Pan American 747, which was invisible in the thick fog, was still on the runway. The Pam American crew saw the lights from the KLM plane approaching them and made a desperate but unsuccessful attempt to clear the runway before the now, barely-airborne KLM plane sliced through them, killing 583 passengers on the two planes (Cushing).

The issue of standardization of language, specifically ATC phraseology, within the aviation industry is one that has been debated for a number of years. Barbara Kanki, a NASA Ames human factors research psychologist and expert in flight-deck communication problems points out that several groups are studying the disparities between worldwide ATC systems. One of their goals is to examine the differences between ICAO and FAA phraseology and to show what is equal to what. "These are gigantic topics and there is no right or wrong. Each country has its own glossary and we are trying to find a variability that is acceptable" (Carlisle 2001)

While the FAA is primarily a U.S. standard, a number of countries, such as Mexico, which routinely fly into the U.S., also use a version of FAA phraseology. As pointed out earlier, ICAO sets the phraseology for most of the rest of the world. ICAO, through its PRICE (Proficiency Requirements in Common English) Group, has taken steps to standardize the English used in all ground-to-air communication (Matthews, 2001). The recommendations for standardization can only be implemented after all 187 member states adopt them. This is not expected to happen before 2008. Many countries are hostile at any attempt to impose English, even when language diversity is demonstrably a safety issue. (Education Guardian, 2001).

ICAO vs. FAA: Examples of Phraseology Differences

The variations between ICAO and FAA standard phraseologies are numerous (Simon 1998). In fact, a number of organizations have published and continually update their lists of these differences in an attempt to keep their pilots and controllers aware of the phraseology variations they may encounter on international flights.. (See, for example, *Glossary for Pilots and Air Traffic Services Personnel*, published by Transport Canada).

The following are just a few of the differences in standard phraseology between these two aviation regulatory organizations (Pilot's Reference 1999):
ICAO: back track
FAA taxi back

ICAO: clear of traffic
FAA: traffic no factor

ICAO: line up and hold
FAA: taxi into position and hold

ICAO: passing

FAA: leaving

ICAO: Report your heading and level
FAA: Say heading and altitude

These differences represent localization issues that must be dealt with by any company that intends to deliver accurate pilot/ATC communication training.

Again, think about the multiple possibilities of communication among pilots and air traffic controllers. Certainly, English language proficiency is a major issue, but so is the need for all of these communicators to be using standard phraseology. With all of the possible international interactions, it is not difficult to understand the need for standardization of Aviation English and the need for rigid proficiency requirements for pilots and controllers (see, e.g., Matthews 1999 and 2001; University of Redlands, 2001). Since a company that is developing Aviation English cannot control international proficiency and standardization issues, it has to deal with the elements it can control.

The Course: Whose English?

Virtual Languages' main issue, therefore, deals with the question: When an aviation training program or aeronautical university recognizes the need for Aviation English training, exactly which form of English should be taught? Can a web-based training program truly be internationalized for delivery all over the world? How can a company adapt web-based training for localized requirements?

That is the situation that faced Virtual Languages when it began to develop its web-based Aviation English product for use all over the world.

Consultation with International Aviation Authorities

In the content design and review phases, Virtual Languages' content team had to determine the best strategy to deal with the diverse phraseology requirements in different locales. They researched regulations of each body, studied phraseology guidelines, examined areas of difference, and interviewed aviation professionals to get insight into phraseology variations and the use of nonstandard phraseology.

In a strong effort to develop the best possible ATC training segment, officers met with officials from both the FAA and ICAO, as well as several European ATC organizations such as Eurocontrol and Belgocontrol, to discuss strategies to handle the need for divergent ATC communication portions of the Aviation English course.

As a result of these discussions, Virtual Languages became strongly committed to developing a product that promotes ICAO standards for ground-to-air communication. However, this can be a difficult goal to achieve in the framework of an Aviation English training program. One issue is that ICAO standard phraseology is not usually taught in U.S. aviation training programs and is not used at U.S. airports, or in all other non-U.S. countries. The FAA sets the standards for the language used in U.S. controlled airspace; therefore, the company has to cope with this fact as a training issue for some customers.

The Solution

Which parts of the course can be internationalized, or delivered to all clients around the world without regional modifications? In fact, all parts of each course – Reading, vocabulary development, and content-based listening activities – except ATC listening – are appropriate for world-wide delivery. There is, however, the caveat that in the current product, VL uses a variety of American English speakers. An alternative version of the courses using British, Australian, Irish, and other non-American-English speakers is planned. The recorded sections include the text of the Reading Selection, key vocabulary words, and feedback for each question at the lower course levels, in addition to the listening activities.

How does the company handle the need for localization of the ATC sections of the course? In fact, our solution is to develop parallel training packages. Because the company's first potential clients were in the U.S. or Mexico, FAA-based ATC communication was used for the first courses developed. The ATC portion of the courses are always based on actual ground-to-air communication, so tapes from the Miami Control Tower were used as the first set. The tapes were transcribed by pilots and the transcriptions were used as the basis for the listening activities. Thus, FAA standard phraseology is the basis for this version of the product.

Although the FAA sets the U.S. standard, we quickly learned that use of nonstandard phraseology is common in U.S.. That presented a new dilemma. We wanted pilots and controllers or aviation students to hear and practice real language in real contexts, so we needed to use tapes from airport control towers. When dealing with actual tapes, how do we handle nonstandard phraseology issues? To deal with nonstandard phraseology, in the feedback for each activity, information will be given about what the pilot or controller actually said, and then what should have been said using standard FAA phraseology.

The second set of courses will be offered with a variety of English accents (British and others) using tapes from European (or other appropriate) towers. Nonstandard communication will be handled in the same way, with the standard phraseology of ICAO used as the model.

The Future

Eventually, ICAO and FAA should come together on one standard phraseology for international aviation. In fact, Virtual Languages has been invited to participate in this ongoing discussions, next at a panel discussion at the Farnborough Air Show in England in July. If the current differences can be resolved through the standardization recommendations of international organizations, then a big step will have been made toward the internationalization of Aviation English training. When this occurs, most of the localization issues will disappear, at least insofar as terminology and phraseology are concerned. At that time, the main localization issues will be reduced to those of dialects, particularly accents, and colloquial or nonstandard use of the standard phraseology.

Until that day in the very far future, Virtual Languages will continue to wrestle with having to develop a web-based training product that is partially internationalized, but that has sections that are localized for specific clients around the world.

Abstract: New tools whether developed organisationally, commercially or within a domain may represent innovation in the workplace and can be part of larger scale reform and change. This paper examines community-based web sites to being built about tools in two distinctly different workplaces. The tools *PRODIGY*, a computerised decision support system and *StageStruck*, a performing arts knowledge construction tool are both recognised in their fields as being innovative in both their use of technology and for their potential to improve the practice within the domain. This paper explores the rationale for developing a web-based communication and resource area to support a community of practitioners in their implementation of these technological innovations. The dialogue explores the demographics, design and development issues faced by community managers charged with promotion and support of these innovative products.

The Rationale for Growing Communities of Practice as On-Line Support

Background

The research and product design detailed here set out to ask what part can be played by well-researched and designed on-line activities in shaping the future of, and meeting the needs for change. Over time the community of practice (Lave & Wenger, 1991) emerged as a complex yet attractive solution and the focus to mapping the development and efficacy of a web-mediated community of practice in advancing implementation of an innovation. The focus of this research explores the roster of issues arising as the theory of communities of practice is applied to a specific cases of on-line professional development of teachers and medical practitioners. This paper is a bounded history of the two research projects and their advancement to date.

The dilemma for the developers of both products was to identify and establish ways to promote the diffusion of these technological innovations and to provide valuable and effective professional development towards implementation for the practitioners who do or plan to use them. The community of practice (Wenger, 1998) model emerged for both development teams as an effective strategy for dissemination and knowledge building around the use of these products. This community of innovators will be supported through a purpose-built Web site designed to afford the opportunities and activities that are characteristic of the making of meaning that is at the heart of the community of practice.

The products in outline

PRODIGY (www.prodigy.nhs.uk) is a computerised decision support system (DSS), which provides evidence-based recommendations for the management of a condition in a clinical setting. It sits within existing clinical computer systems and integrates with the electronic patient record. It is in itself an innovation and is part of a reform to the use more of evidence-based medicine (EBM), guidelines and protocols and the computer within the consultation to access this information.

STAGESTRUCK *(www.stagestruck.uow.edu.au)* is recognised as an innovation in the teaching of the performing arts. It is an innovation both as a constructionist multimedia technology for creative and performing arts teaching and learning. More broadly it has been recognised as a pedagogical innovation because of its constructivist underpinnings and the design realisations as a multimedia knowledge construction tool (Hedberg, 1997). In both cases the innovation is a new computer-based tool and that tool that is part of a reform process as well as an increasing application of technology in the practice.

The Theoretical Basis for Community of Practice

Whether change is based on the 90's call to the 'learning organization' (Senge, 1990) or the new millennium's 'knowledge-based organization' (Wenger, 1998), the key to reform appears to be the way the organisation values knowledge and its management. Botkin, (1999, pp.3-4) states 'Good ideas are knowledge waiting to be tapped, and it's the trademark of a smart organization – a fast company – that it knows how to honour and legitimise the tacit knowledge that its people have stored up in their work practices and make it visible.'

Wenger contends that the sharing of tacit corporate knowledge is vital to the organisational success. The knowledge Wenger speaks of is not static. It cannot be fleshed out and then documented in a set of guidelines nor distilled into a discrete data set and stored in an information retrieval system. It is that practitioner knowledge that those in the field, workshop or classroom share on an ongoing and usually need-to-know or need-to-share basis. Co-workers help each other to solve problems, affirm actions, seek new challenges, and in doing so advance the goals of the organisation and the practice.

A community of practice specifically centres its interest on the practices of the workplace. McDermott (1999 pp.1) simply and succinctly distinguishes the community of practice from other types of communities. 'But communities of practice are not just celebrations of common interests. They focus on practical aspects of a practice, everyday problems, new tools, developments in the field, things that work and don't.' While these communities are obviously not new the recognition of their value to education and industry is. In a summary of complexity theory and educational change processes, Fullan (1999, pp.15) supports Wenger's contention about the value of sharing tacit knowledge. 'In brief, the secret to success of living companies, complex adaptive systems, learning communities or whatever terms we use, is that they consist of intricate, embedded interaction inside and outside the organization which converts tacit knowledge to explicit knowledge on an ongoing basis.'

Given the community of practice seems to lend itself as a model for dissemination and professional development, the next question became; How can that community be developed and /or supported on-line? It is necessary to explore each of the individual innovations and their on-line stages of development towards community to see how similar these two disparate communities really are.

The Tools Examined *Product 1: PRODIGY*

At the present time PRODIGY can be used by General Practitioners (GPs) in England and has the potential, subject to legal changes, to be used by other health professionals such as nurses and pharmacists. There are various potential uses of PRODIGY including during a consultation to provide options for prescribing, non-drug advice, patient information leaflets and referral advice. It also includes referenced clinical information to access outside the consultation, enabling GPs to keep up to date and abreast of the latest developments in prescribing and healthcare.

The PRODIGY project team consists of Research and Evaluation, Software Development, Authoring and the National Dissemination Office (NDO) (www.schin.ncl.ac.uk). These groups are crucially interdependent in developing the technology, updating clinical content and promoting PRODIGY use amongst the GP community. The NDO model of dissemination is based upon an integrated approach of communications and marketing, training and education and support (Figure 1).

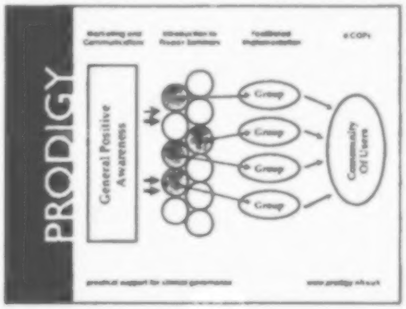

Figure 1 The PRODIGY Dissemination model developed and implemented during 2001

The support element of the model comprises the website, including access to the clinical guidance, education and training materials, GP system supplier specific information and the development of an on-line community of practice (e-CoP).

The Domain and Practice

GPs work predominantly in an individualistic way characterised by a high level of autonomy their in decision making. As a discipline they tend according to McWhinney (1996) to define themselves in terms of their relationship with the patient, which takes precedence over a more mechanistic approach to medicine. The effect of this value on relationships, places experience rather than disengaged reason, at the heart of general practice decision-making where he argues, *"experience engages... feelings as well as... intellect"* (McWhinney, 1996, p433). The impact of these characteristics is likely to affect the decision-making processes specifically in relation to the use of evidence-based medicine (EBM), guidelines and protocols and the use of the computer within the consultation to access this information.

The use of EBM by GPs has been identified as problematic (Mears & Sweeney, 2000; Cranney et al, 2001) displaying GPs mistrust of the research and it's applicability in a specific patient context. In this respect GPs may regard PRODIGY as a threat to the more traditional and intuitive ways of working and GP autonomy in decision-making. With this in mind, the community of practice being developed for PRODIGY users aims to facilitate a forum through which GPs can share their views and knowledge about using PRODIGY in a practical environment. This also provides an opportunity to discuss the application of PRODIGY in relation to other NHS goals such as National Service Frameworks (NSFs), Clinical Governance (CG) and re-validation.

BEST COPY AVAILABLE

On-line Community of Practice Design (e-CoP)

The PRODIGY website has been designed to reflect the multi-faceted nature of PRODIGY not merely as a decision support tool, but in providing referenced material used in the production of the guidance, patient information leaflets, and background information about specific conditions listed in PRODIGY. Whilst GPs may commonly use the computer for routine tasks such as repeat prescribing, the use of the computer during the consultation is less frequent (SCHIN, 2001a). The website aims to offer practical contextual support and information in relation to using the computer in the consultation (UCCR), as well as highlighting how using PRODIGY will support GPs in relation to Clinical Governance and National Service Frameworks.

Three types of visitors to the website are envisaged; *non-users but potential users* who are seeking information about what PRODIGY is, what it does and how they can use it. *Current users* who are seeking ways to use PRODIGY in a broader context; and *non-users* interested in promoting and facilitating use, for example Primary Care Trust (PCT) trainers, GP Clinical System Suppliers. One of the functions of the website is to provide training support, information about how PRODIGY can be switched on, and how PRODIGY can be recognised on the different GP computer systems. Therefore the website and the development of the community of practice is intended very much as an ongoing support service to users and potential users of PRODIGY.

In the first instance the aim is to develop, facilitate and sustain an electronic community of practice for users described above. The methodology and framework, which will be formulated during the development of this user group, can then be used to extend the e-community to other groups within the UK healthcare domain. It allows anonymity amongst users, with the potential for different professionals to communicate more freely (i.e. GPs and nurses) in a relatively safe environment. Initially a member of the NDO team and a GP working for SCHIN will facilitate the e-Community of Practice. The structure of the e-CoP is based on asynchronous message boards, email lists and a messaging tool, rather than a chat facility.

In order to access the current PRODIGY community of practice users have to be registered and given a login. This has been kept deliberately simple at this stage so as not to deter users from registering, and currently identifies to SCHIN staff the email address and professional group of the user. Since the commencement of registration in February 2002 the number of registered users at July 2002 was approaching 3000. This figure continues to increase with an average of 80 new registrations per week. The benefits of being a registered user are; access and potential to participate in the message boards; ability to register for a discussion list; and an onsite messaging tool enabling users to make direct contact with other registered users, without disclosing personal identities.
Users will eventually have a profile around key interests[1] of users and encouraged through the facilitators to generate discussion topics within and between different participants. Invited 'experts', for example PRODIGY GP Champions, technical IT people, and clinical authors will also be used to lead particular discussions around their area of interest. Registered users will be encouraged to submit further detailed information through the use of the online message tool, normal email to all those who have given permission to receive more PRODIGY information, and online banners and bulletins on the PRODIGY site.

Through the extension of the user profiles registered users will also be able to search for other community members with specific interests, enabling the organic growth of communities. It is hoped that through the growth of such communities the development and transfer of knowledge will take place both within the community and to the "outside world" including informing further PRODIGY development.

The steady increase and high numbers of registrations is very encouraging although further work still needs to be done to ascertain their actions whilst on the site. Despite this the use of the message board and email lists have been slow to develop. It is not unusual for it to take time for such tools to be fully embraced, or for communities to shift from a demographic group to being a network (Diagram, 1). The planned facilitation is to continue to encourage use through the website, but to also be aware of any hot issues arising that might provoke discussion or the need for GPs to communicate quickly and directly. Plans are afoot to place a news banner containing the latest health-related headlines and provide a link to the message board to encourage discussion around this topic.

---

[1] Cancer Referral Advice, Cardiovascular System, Dermatology, Eyes and Ears, Gastrointestinal, Haematology and Endocrine, Infection, Injuries, Neurology, Obstetrics and Gynaecology, Psychiatry, Respiratory, Rheumatology and Orthopaedics, Urology

This is only the beginning of the establishment of an online community of practice, but feedback is constantly sought from users through the message board and email lists. The future development of PRODIGY will be to encourage use by different health professionals (i.e. nurses and pharmacists) as well as GPs, and this might provide new and different needs from users.

The PRODIGY e-CoP project is still in the early stages and whilst modelled on existing communities of practice and experiences, the success and growth of such a community cannot be foreseen, and will largely depend upon the shared needs and experiences of the community itself. However, the role of the facilitators is to try and establish the framework and support as necessary conditions to enable it to take place. It will be a learning experience for all those concerned.

The Tools Examined Product 2: Stagestruck

STAGE STRUCK
STAGE STRUCK

Figure 2 StageStruck Online Community Design

StageStruck, produced by Wollongong University and National Institute for Dramatic Art (NIDA), was one of 10 CD-ROMs produced in *Australia on CD* as a Creative Nation[*] federally funded Cultural program. Over $AU6 million was committed to produce 10 CD-ROMs designed to bring Australian culture to the public using new media technologies. Sadly it was never intended nor were any resources committed to any promotion or professional development for teachers in each or any of these products. Copies were distributed to every school in the country in the first semester of 1999. *StageStruck* has been recognised as an innovation in the performing arts. It is an innovation both as a multimedia technology for creative arts teaching and learning. More importantly it has been recognised as a pedagogical innovation because of its constructivist underpinnings and design realisations as a multimedia knowledge construction tool (Harper & Hedberg, 1997). Despite widespread distribution and acclaim, having won several prestigious Australian and International awards (AMIA 1999, BAFTA and EMMA 1998), preliminary discussions with educators indicated that many (perhaps most) are unaware of *StageStruck's* existence let alone its educational benefit.

The Domain and Practice

While healthcare reforms might seek a move to more evidence based medicine, educational momentum moves toward the creation of more constructivist and constructionist learning environments. Tools are being developed to motivate new teaching practices and support constructivist student-centred learning and StageStruck has been recognised an exemplar amongst those tools. In-service teachers are in many ways as independent and inexperienced with, and mistrustful of, new technology as many medical practitioners. Reilly sums up the in-service teachers' lack of connectedness graphically when he states that; *Educators are "islands of excellence" with no ferry service to connect them to each other or to groups of their peers.* (Reilly 1999 p60)

BEST COPY AVAILABLE

The group being formed around StageStruck might develop into a community or the Web site might stand to service smaller face-to-face communities in the in-service domain. This K-12 creative and performing arts community did not exist before people were drawn to become members on-line. While members are likely to each belong to other communities and they may have ties through these to some members on-line, no one community already exists that ties all the disparate groups (primary, secondary, drama, dance, design, creative arts, English) and distributed individuals together. They do more correctly constitute a demographic group (Andrews et al, 2001 pp.1) with the potential to become a community if ties and roles can be effectively established through the on-line engagement and collaboration.

Adoption of curriculum and pedagogical uses of technology in schools has been slow and inconsistent. This lack of adoption can be linked directly to the lack of resources devoted to in-service teacher professional development or to the ineffectual nature of the training offered. Teacher needs in relation to ICT beyond access to the technology (hardware and software) have consistently been for effective professional development with explicit links to curriculum and the "stuff" of classroom teaching. As hardware and high speed connectivity becomes more readily available in classrooms, educators are turning to focus more on the issues of support, ongoing professional development, recognition of ICT skills and leadership, accreditation for high level skill development, access to high quality resources and equity delivery formats and languages.

The National Foundation for the Improvement of Education Report *Teachers Take Charge of Their Learning* (NFIE 1996 pp.1) asserts that; *To improve student achievement, public schools must weave continuous learning for teachers into the fabric of the teaching job. This work can and should be initiated by the teaching profession itself in partnership with other educators, communities, districts, and states.* There is an imperative for new professional development strategies and for teachers themselves to take control of their personal professional development. For the past ten years it has been recognised that a 'culture of collegiality' is required. This can be achieved through an environment where teachers teach teachers in a supportive network of practice. (Little 1993, Lieberman & Miller 1991, Warren & Roseberry 1992). There are no simple remedies, but it does seem understood that communication and collaboration are two of the keys.

On-line Community of Practice Design (e-CoP)

The symbiosis between education reform and the integration of technology into learning is profound: technology requires the rich learning environments envisioned by reformers; reform demands the power of technology to put people at the centre of their own learning. (Serim, 1996 pp.1) Having established that there is value in community development and its potential for ongoing professional support, it is important to examine the circumstances under which the community of practice could effectively go on-line.

At present stage of development the group being formed represents a potential community. Andrews et al (2001 pp.1) describe these potential groups. *Demographic groups normally do not constitute communities. However, they have the potential for becoming on-line communities when individuals share common interests, needs and goals, have a desire to communicate with a peer group, and can easily find each other to establish relationships.* The StageStruck On-line Community is taking the demographic group of K-12 teachers of the performing and creative arts and linking them together firstly through an on-line network then through to an opportunity to build community with active facilitation and support. This growth from a distributed set of individuals in contact on-line through to a loosely tied network for sharing and on to a fully-fledged collaborative community is a lengthy process determined by the effectiveness of the management and facilitation and the commitment elicited over time from the members.

Diagram 1: The forming of communication and collaboration between individuals toward community (Stuckey et al, 2002)

It has taken two years in planning and web design and development and promotion to get to what Wenger (1998) describes as the second phase of community development; Coalescing. The focus of 2000 was the research, literature review and study of cases of on-line professional development and the design of the web site in response to teacher needs and concerns. During this year contacts were made and groups identified that might be integral to design of and dissemination about the community site. Finding out just who is in this demographic group has proven to be an ongoing task. In 2001 the development of the architecture became the focus. Advertising the site and reaching out to teacher groups to elicit membership and teacher concerns about focus innovation CD-ROM technology. Establishing a critical mass of members for the network and connecting those people through the web site has taken much longer than was anticipated in this phase. There were 200 members of the site at the time of this publication.

In the naivety of the web design model, the author fell into a trap that has no become legend to those involved in community development. While it is possible to build a static Web site, advertise it well and have thousands of hits follow, community success is both much slower and much more human-to-human interfaced. Users were registering, they were using the examples and demonstrations but they were not communicating with the mangers not with each other. When users were found to not be contributing or sharing, it became necessary to revisit those successful cases of community and find out what necessary to revisit those successful communities and delve deeper into the cases by interviewing community leaders, facilitators and mangers. It became evident that larger group open communication was not the way to start, and this was especially true with teacher communities. All evidence pointed to the need for small more purposeful nodes within the larger community as a way to start the development of bonds and identity within the community. It was about comfort and trust.

In mid 2002 members will see the main activity, communication, collaboration and facilitation is targeted specifically toward community building in smaller group activities. Early adopters of StageStruck are being invited to join projects and to work in teams to produce curriculum support materials for the community and to mentor new users. It is hoped that new users will find the community a safe place to seek technological and pedagogical support and to celebrate the use of StageStruck through the publishing and sharing of student works and teaching resources. Various groups within the performing arts community are to be given areas of the site to make their own and to develop new events, ideas, projects and resources. Initial facilitation on the site will come from the author and researcher, an experienced practitioner from within the domain. Eventually it is hoped that facilitation can be devolved to the community members and indeed that the members will contribute to and design the new spaces and facilities of the site in the future.

In summary

It is argued that computer mediated communication cannot build a community. (Weinrich, 1997; Fernback & Thompson, 1995) and Wenger himself describes establishing communities of practice as 'the art of balancing design and emergence' (Wenger, 1998 pp. 9). Sharp argued that the literature on on-line communities points to '...a weaker sense of community, a discourse commu nity' (Sharp 1997 pp. 6) and he went on to advance a set of actions likely to increase the success of communities of practice. These actions include face-to-face activities and groups wherever possible and opportunities for short-term mentoring. Even in the highly technological environment of the Internet we can see that technology alone cannot support all that true community requires.

It remains to be seen whether the rationale and carefully researched and socially supported on-line structures represented here will develop a level of commitment and engagement that can be described as community or whether as a network they will serve to meet the needs of the practitioner innovators that they seek to serve. There are many technological innovations that need to provide effective pathways and environments for adoption and implementation There are many demographic groups consisting of distributed and independent individuals like medical practitioners or in-service teachers that could be served by the effective design of communication and community built through on-line engagement. The understandings and lessons to be learned, over the next year, as these two projects apply the communities of practice theory to affordances of on-line technologies will have ramifications for those seeking effective long term strategies for adoption of many tools of innovation.

Footnote: The authors of this paper met in the **Foundations of Communities of Practice** workshop lead by Etienne Wenger. [http://www.cpsquare.com/edu/foundations/index.htm] This event is significant for it is the topic of community that brings knowledge managers, facilitators, educators and researchers from industry, education, government and non-profits organisations together. It did not take long to realise that supporting medical practitioners to embrace a technology in their evidence-based medicine was not unlike bringing teachers of the performing arts to embrace technology in their teaching of creativity. Indeed after some examination of the concerns of both groups the likeness became even stronger. These similarities will hopefully continue to be drawn out as the research progresses. The authors would be keen to join with any other designers seeking to support the use of innovative technological tools.

Accessing Distributed Learning Repositories through a Courseware Watchdog

Abstract: Topics in education are changing with an ever faster pace. Especially in the field of life-long learning the aspects that need to be taught by information providers must keep up to date with emerging topics. The courseware watchdog is a comprehensive module which allows users to focus on existing subfields of a discipline, but thereby be aware of important drifts and tendencies in the field.

Introduction

In many domains, knowledge is becoming obsolete with an ever faster pace. Therefore, life long learning is gaining high importance for employees in order to keep up-to-date with recent developments in their respective fields (Fischer 2000). For supporting life long learning, E-Learning plays an important role in enabling on-demand learning of the individual employee (Maurer & Sappe 2001). However, only having online access to predefined course material that is stored in a single centralized repository does not meet the needs of such a learning scenario. Rather, the E-Learning approach should support the tailoring of the learning material to the specific needs of the employee being determined by the task at hand and his or her previous experience (Nejdl 2001). Furthermore, the individual learner should be able to keep track of recent developments and new trends in the relevant domains.

The same holds for lecturers, as the life cycle of courseware becomes shorter, and new courses on upcoming topics have to be offered more and more frequently. As there do not yet exist 'classic' text books on these topics, other ways to obtain new courseware material have to be gone. One relevant information source is of course the WWW; but as in old times one will also contact peers, i. e., lecturers and researchers working on the same domain, and ask them if they can help out with some material. As an individual learner, the lecturer benefits from technical support in accessing and tailoring these sources, and in discovering new trends.

The Courseware Watchdog that is described in this paper addresses these challenges by a comprehensive approach that exploits concepts from the Semantic Web, such as ontologies, in an E-Learning scenario (Stojanovic et al 2001). It is part of the PADLR framework (Personalized Access to Distributed Learning Repositories) that builds upon a peer-to-peer approach for supporting personalized access to learning.[1]

Figure 1: An ontology about research and teaching topics.

Ontologies are a means of specifying the concepts and their relationships in a particular domain of interest. Thus, they facilitate the sharing of knowledge between actors (Staab et al 2001). A small example of a learning ontology is shown in Figure 1. The left side shows the concept hierarchy. 'Assistent' is for instance a sub-concept of 'scientific_staff'. The upper right box shows the instances of this concept (e. g., 'Stefan_Decker'), and the lower right box shows the relationships the highlighted instance has to instances of other concepts (e. g., 'Stefan_Decker teaches semantic_web_technologies'). As we will see below, this formalization will help to also find the homepage of Stefan Decker when one is searching for course material related to the Semantic Web.

The Courseware Watchdog aims at finding and visualizing relevant educational material on the WWW and in the peer-to-peer network according to the user's needs, and detecting trends and changes within the field of interest. The Courseware Watchdog consists of the following components (see Figure 2):

- A *focused crawler* will find related web sites and documents that match the user's interests. The crawl can be focused by checking new documents against the user's preferences as specified in terms of an ontology.
- Integration into the *Edutella framework* enables the user to annotate educational resources with metadata to support exchange in the Edutella peer-to-peer network.
- As different users may have different points of view, *subjective clustering techniques* are used to generate subjective views onto the documents.
- *Visualization and intelligent browsing* capabilities for the results of the crawling and clustering steps will be provided.
- These tasks are supported by an underlying ontology. In order to reflect changes and trends within the field of interest, ontology learning methods will be employed to facilitate *ontology evolution* (Stojanovic et al 2002).

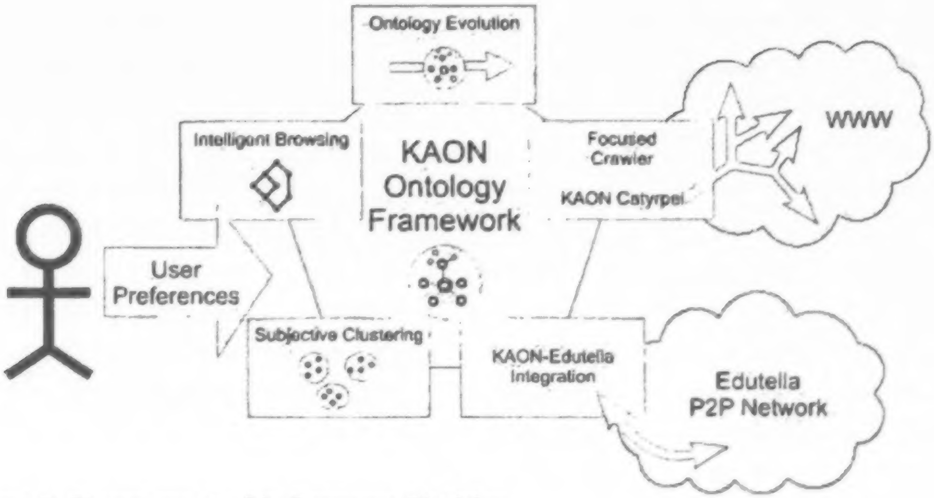

Figure 2: The components of the Courseware Watchdog.

These components are connected through the Karlsruhe ontology framework KAON (Handschuh et al 2001). KAON provides a plug-in infrastructure for ontology-based tools and applications.

The components are discussed in detail in the remainder of the paper, and are illustrated by a running example: consider a lecturer who has to prepare a new course about the semantic web. Although our lecturer has no course material in that field, she is confident that she will find relevant material either on the WWW or from colleagues working on that domain.

The rest of the paper is organized as follows. The next two sections discuss the information sources: the first presents the focused crawler and the second the Edutella peer-to-peer network. The following three sections discuss the treatment and interaction with the courseware collected and address the following components: subjective clustering, intelligent browsing, and the ontology evolution. We then conclude the article.

Focused Crawler

A web crawler is a program that collects data from the web automatically by following links extracted from web documents. Thus, a portion of the web is traversed in a breadth-first manner, usually without regarding the relevance of the collected documents with respect to the user's needs. In order to restrict the traversal to material relevant to the user, the crawling process can be *focused*. Focusing in this context means preferring those links in the crawling process that appear to be pointing to relevant documents.

KAON Catyrpel (Maedche et al 2002a) is an ontology-based focused crawler embedded in the KAON environment for ontology-based tools (Handschuh et al 2001). With Catyrpel, the user can specify topics of interest in terms of an ontology. The user's preferences, i. e. entities in the ontology, and the ontology itself are then used to compute the relevance of documents and hyperlinks. After simple linguistic preprocessing (HTML tag removal, stemming etc.), lexical entries of the ontology are matched against the text and a relevance score is computed. Through the use of the ontology structure a useful measure of relevance can be evaluated, even if no exact match can be found. Several relevance measures can be used, which compared favourably against breadth-first search or simple keyword-based measures.

BEST COPY AVAILABLE

When searching for "Semantic Web", the focused crawler may for instance come across the web pages of Stefan Decker at Stanford University, who has already annotated his pages with RDF statements saying that he is giving a course 'Semantic Web Technologies'. The crawler will add the instances to the knowledge base used by the ontology as shown in Figure 1, and will return the homepage with a certain score.

Integrating the Edutella Peer–to–Peer Network

The Courseware Watchdog includes the possibility to access the Edutella peer-to-peer network (Nejdl et al 2002a). Peer-to-peer (P2P) networks are decentralised networks, which allow for publishing and searching resources based on direct collaboration between its nodes.

The Edutella network applies the P2P paradigm to the exchange of structured information about available learning resources.[2] A common data model facilitates the integration of data sources such as relational database systems or XML and RDF repositories. Thus, all of these can act as Edutella peers, either as repositories or as consumer of the network resources.

For instance, our lecturer may query Edutella. She will be then able to locate relevant material on the P2P network which has been provided by other Edutella users. This way, she may for instance come across further lectures and tutorial about the topic. Moreover she will be able to control and share her own resources by annotating her resources with the annotating tool contained in the KAON framework (Nejdl et al 2002b).

Subjective Clustering

In order to detect trends and tendencies in collections of courseware material, it is necessary to find outliers or groups of outliers. Because users typically do not want to exactly specify their complete profile and because users' profiles tend to change rather often (which is a major problem for recommender systems), we want to give the user views onto existing educational media. Conventional clustering techniques provide a first answer for this purpose.

Typically, however, clustering is used to give a single, "optimal" view on (learning) components. This is not suitable to account for the plurality of views that exist when looking at educational media. We have recently developed clustering mechanisms that allow to provide *subjective views* onto documents (Hotho et al 2001), which are based on an underlying ontology.

For instance, one view may concentrate on differences and similarities of the content of learning material, while another view may concentrate on its presentation form, or on the levels of skills and experiences needed. The lecturer can then use the first view to select the material which addresses the topics which are most relevant to her planned course. She might also use the second view in order to see how the material is distributed over different types of material like presentation slides, exercise sheets, or online demonstrations.

Browsing of Watchdog Data

The results from the crawling and clustering process need to be visualized in order to provide easy access for the user. The browsing component of the watchdog is designed to be based on techniques from Formal Concept Analysis and Open Conceptual Hypermedia in order to visualize the similarities and differences between documents and clustering results through lattices.

---

[2] http: //edutella.jxta.org

Formal Concept Analysis (Ganter & Wille 1999 & Stumme & Wille 2000) is a conceptual clustering technique which provides a hierarchy of concepts. When applied to learning material, the multiple inheritance within this hierarchy provides a rich conceptual landscape for navigating and retrieving the educational media. In particular, it allows to combine the different views created in the subjective clustering step; for instance to find first the most relevant clusters of documents, and second among them the slide presentations to set up the course.

We have recently implemented a Conceptual Email Management system (CEM) which supports exactly this navigation in collections of emails (Cole 2000). Our next step is to extend this approach to courseware material and other documents. This follows the vision that in the near future file, document, email, and web browsers will become tightly integrated in one unique user interface.

While Formal Concept Analysis focuses on the hypernym hierarchy on the concepts, Open Conceptual Hypermedia also considers arbitrary relations between the concepts (Goble 2001). It aims at enriching a web-based open hypermedia link service with semantic knowledge provided by ontologies. By combining both Formal Concept Analysis and Open Conceptual Hypermedia in the user interface of the courseware watchdog, we support thus navigation along both hierarchical and non-hierarchical conceptual relationships. For instance, the lecturer can continue his navigation from the cluster of relevant courseware material as obtained above by following the link 'created_by' to the creators of that material, and then follow on to the projects 'led_by' these researchers. There she may find additional presentation material to illustrate her lecture.

Ontology Evolution

The Courseware Watchdog as presented in this paper so far builds heavily on a proper ontology that reflects what the user is interested in. However, over time such interests will invariably change together with the teaching/learning subject itself. Therefore, the ontology and the topics represented therein need to be updated and one must deal with several requirements incorporated in such updates:

Introducing new concepts: The first requirement is about (*i*) recognizing that a new concept (e.g. a new topic) has appeared in the course material available in the network or on the Web, (*ii*) inserting this concept into the right place of the taxonomy, and (*iii*) linking it via further relations to other concepts.

For instance, Web Services are today an emerging topic, and will probably have to be included in future courses on the Semantic Web. Hence 'Web Services' has to be recognized as a term that denotes a new concept. It must be inserted into the concept hierarchy (e.g. as a subarea of computer science) and it must be related to other disciplines (e.g. to business process modeling and E Business). Only if this has been done the concept can be used by the courseware watchdog. Some example methods for this are proposed, e.g., in (Maedche et al 2002b).

Recognizing concept drift: The subject of "Semantic Web" is currently in flux and the understanding of it will evolve over time (such as that of other disciplines). In order to use the concept appropriately it will be necessary to adapt the concept to its current use (Klenner 1994).

Versioning ontologies: Even when there are ontologies at different points in time, it should be possible to relate them, e.g. in order to explain why "Artificial Intelligence" in the 1970ies included computer algebra, but does not anymore in 2002. For this one needs comprehensive means for versioning ontologies (Heflin & Hendler 2000).

Process: Eventually, updates, drift and versioning will not happen completely automatically. Rather, they will require an organizational process that safeguards critical changes (e.g., deletions of large parts of the ontology). Thus, one needs a process model and tools to handle the process. Some first models exists (Maedche et al 2001, Staab et al 2001) but they need to be refined and adapted to E-Learning needs.

The combination of the different requirements will allow to exploit the benefits of the courseware watchdog, the central objective of which is to facilitate that the lecturer remains up-to-date about the courseware he is responsible for.

Conclusion

The Courseware Watchdog is a comprehensive approach for supporting the learning needs of individuals in fast changing working environments, and for lecturers who frequently have to prepare new courses about upcoming topics. Being based on the Edutella peer-to-peer network the courseware watchdog provides personalized and flexible access to learning material that is offered somewhere on the Web. This functionality is achieved by tying together focused crawling, subjective clustering, flexible conceptual browsing, and ontology evolution.

The components of the envisioned courseware watchdog need further improvement. For instance, focused crawling has to be improved by offering further measures for computing the relevance of documents based on the ontologies and available metadata, and ontology evolution needs further techniques for better reflecting changes in the underlying learning material. Morever, we are also working on a better integration of the diverse functionalities to combine the diverse functionalities of the components.

Nevertheless, the courseware watchdog indicates how a Semantic Web based approach is better able to meet the needs of today's and future learning scenarios.

CoCoFolio: A Web-based Electronic Portfolio for Enriching Students Learning by Collaboration

Takeshi Sugiyama, Naoyuki Kakehi, Tsuneko Kura, and Tokiichiro Takahashi
NTT Cyber Solutions Laboratories, Japan
{sugiyama.takeshi, kakehi.naoyuki, kura.tsuneko, toki.takahashi}@lab.ntt.co.jp

Abstract: *We have developed a web-based electronic portfolio, called CoCoFolio, for enriching students learning by collaboration. It consists of two collaboration tools: a multi-layered drawing tool, called "CoCoBoard", and a small bulletin board, called "Discussion Board", for each student's submission. These tools support a series of expression activities: expression, sharing, peer-review, coaching, and reflection. CoCoFolio was implemented in two applications, in a university and in a junior high school, and it was found to improve students' motivation, increase students' knowledge through peer collaboration, and improve their learning process.*

1. Introduction

A portfolio, which is a collection of student work that represents student's efforts, progress, and achievements, has become popular in K-12 and higher education. It offers many possibilities for learning and assessment. Digitizing portfolios (i.e., electronic portfolios) brings the following benefits: (1) operations such as search, copy, and replace become easy; (2) student-learning processes become open to others; (3) teachers can understand how each student is making progress with their studies and can advise them individually.

There are many electronic portfolio programs available such as HyperStudio [HyperStudio], Florida State's Career Portfolio [FSU Portfolio], Stanford's e-Folio [E-Folio] and ePortfolio consortium[ePortfolio]. The first one is a multimedia authoring tool that enables students at all grade levels to create and enjoy their own experiences in learning. The others are web-based portfolios designed to enable students to portray, and instructors to assess, their learning experience in an integrated, sharable format. They are very effective for archiving and sharing learning experiences of all students in various forms of media; however, they provide few tools for collaboration between students or between students and teachers. Without such collaboration, there is a possibility that students will not reflect sufficiently on their work, and without student reflection, portfolios become a mere collection of student work and much of their learning value is diminished.

In response to these problems, we have developed CoCoFolio, that is , an electronic portfolio for enriching student learning by means of collaboration tools. This paper describes the concept of CoCoFolio and explains the implementation of two pilot applications using it.

2. Concept

To explain the concept behind CoCoFolio, first, expression activities involved in learning are explained in the following. It is very important for students to understand themes deeply and acquire knowledge. In addition, Japanese school education has changed its focus from "passive understanding" to "active understanding".

A series of expression activities represent the relation between one student and others. Basically, to think deeply about a study theme, it is important to put one's thoughts together, then express and reflect on them by oneself. In addition, for students to broaden their knowledge, it is important that they share all learning results with peers and stimulate each other. These expression activities can be divided into the following four stages. By repeating these stages, students can develop certain abilities.

- Expression: A student thinks over a study theme, puts their thoughts together, and presents them.
- Sharing: All students share learning results with peers and get a different perspective on their way of thinking.
- Peer-review and advice: Peers review each other's results and comment on each learning result. Teachers advise all students separately in face-to-face talks.
- Reflection: Each student reads the comments and advice and reflects on their learning results.

1. Submit learning results
Digital camera

Fig. 1 Overview of CoCoFolio

CoCoFolio supports each stage of the expression activities by using information technologies as follows.

- Expression: It can provide students with a common space on the Internet to share their learning results.
- Share: It can accumulate all learning results in a database and share them with others.
- Peer-review and advice: It can provide peers and teachers with collaboration tools for commenting and giving advice on each student's work.
- Reflection: It enables a student to retrieve their own learning history easily.

Moreover, management tools are very important to enable teachers to make original classes according to their own ideas. For example, learning management can provide teachers who have little database knowledge with a management tool for editing subjects, learning themes, user assignments and so on easily on the Internet.

3. Implementation

3.1 System overview

With the above-mentioned concepts in mind, we have developed a student portfolio called CoCoFolio, which consists of the Internet, a web application server, a database, and collaboration tools. Figure 1 shows an overview of CoCoFolio, which utilizes WindowsNT Server 4.0 as the operating system and Oracle as the database. The server software is an extension of our educational software "CyberPedia" [Kakehi 2002]. To use CoCoFolio, a user only needs a web browser like Internet Explorer. Teachers and students can therefore easily access the system from school or even from home.

3.2 Data structure of CoCoFolio

Figure 2 shows the data structure of CoCoFolio. At first, teachers make a learning space by inputting "Year", "Subject", and "Theme", whose relations are similar to directories of a file system. Then, they add some detailed information to the learning theme, such as theme explanation, time limit, and assignment of the students.

The assigned students make their own "Creation" space under "Theme" for submitting their works or creations. "Submission" data is automatically created when the students send their works by a template on a browser. The template allows them to submit a series of "Contents" which consists of a "MediaFile" like JPEG or MPEG, creator's comments and detailed information about submission. Teachers can make their "Correction" directly to each content by using "CoCoBoard" (which is explained in the next paragraph) and write comments by using "Discussion Board" which is like a mini bulletin board [illegible] submissi[illegible] [illegible]ated until the teacher gives [illegible]valuation in terms of a pass mark.

Basically, the default status of submissions is private, but the teachers can change the stat[illegible] t[illegible]ic and post work on the Internet according to the student's will. Peers can view the opened submission on the Inter[illegible] write comments about each other on the Discussion Board. By reading other[illegible] and submissions, [illegible]ents can reflect on their own learning and understand viewpoints of many diffe[illegible].

3.3 CoCoBoard: a Multi-layered Drawing Board

To support a teacher's intuitive [illegible] emplo[illegible] [Sugiyama 2001], whi[illegible]llaborative electronic whiteboard using Scalable Vec[illegible] (SVG) o[illegible] vector graphics [illegible]at. Co[illegible]Board has the following

features.

- Shared whiteboard by means of SVG format: Because of its XML-based format, it is easy to convert or reuse other data and to add metadata to drawing objects. Additionally, the SVG format is less demanding than other raster formats such as JPEG and makes it convenient to communicate using the Internet.
- By means of ActiveX component, CoCoBoard is available on the web and can be used in several applications easily.
- Synchronous or asynchronous communication can be customized according to the collaborative situation on demand.
- Multi-layer canvas architecture provides multiple layers and each layer can be set by teacher, so readable or writable access are available (or both). Even if a student has permission to several access layers, they can view any layer they want by selecting or overlaying them.

By using CoCoBoard, teachers directly overwrite their corrections on a student's work on the Web. It is very convenient for teachers to overwrite directly without running other drawing tools. When the teachers finish overwriting, they upload their corrections via the Internet in asynchronous mode. The CoCoFolio server receives and stores them in a database. Students can view the teacher's corrections by using Adobe SVGViewer and learn something from them. The multi-layer canvas architecture enables teachers to overwrite their corrections on each separated layer. It is therefore possible for students to be coached by several teachers; this is called "team teaching". This function enables teachers and students to learn something from other teachers' coaching.

4. Application examples

To test the performance of CoCoFolio, we asked teachers in Kyoto Seika University (KSU) and Oizumi Junior High School (Oizumi), attached to Tokyo Gakugei University, to use it for supporting their lessons using CoCoFolio. In the KSU experiment, CoCoFolio provided solutions for art and design education, called "Manga University", ("Manga" means cartoon or comic in Japanese.) In the Oizumi experiment, CoCoFolio was applied to "Integrated study" for secondary education.

4.1 Application to art and design education: "MANGA University"

These days, even though there are many web-based education systems, there are few systems for art and design education. This is because it is difficult to aid it by information technology because of its unique features, such as face-to-face coaching and direct coaching through artistic creations. CoCoFolio was applied to solve the trade off between face-to-face coaching and temporal/spatial restrictions.

This experimental project started in May 2001 and involved about 40 students. The workflow of Manga University is as following: (1) The teachers create the themes and assign students. (2) The assigned students submit their scanned creations to the server. (3) The teachers view, modify and comment on each creation by using CoCoBoard. (4) The students view and respond to the teachers' coaching and comments. (5) The students submit new creations.

As shown in Fig. 3, the teacher can directly coach student's creations on the Web. The teacher can coach the students remotely anytime, anywhere, at his convenience. Manga University also allows everyone to easily share the coaching of several teachers. Moreover, it enables students to look back over the past and refer to their history as a personal portfolio.

4.2 Application to various subjects in a junior high school

In Japan, K-12 school education has introduced "Integrated study" styles - similar to the project-based learning in the United States - into the curriculum at the beginning of 2002. It aims to help children develop the capacity and ability to discover problems by themselves and solve them appropriately. The key points of integrated study are that it must be linked with each subject such as mathematics and science and it must guarantee deepness of students understanding by means of expression and reflection.

In this application, the Oizumi teachers use CoCoFolio linked with various subjects. This experimental project started in December 2001 and about 130 students are participating in it over a school year. The subjects are science, mathematics, Japanese, and art. Each subject is provided according to the teachers' original ideas. Examples of these classes are given in the following. Note that submitted work from all students (including comments in Discussion Board) becomes the objects of assessment by teachers.

(a) Science class

This 7th-grade learning theme is "plant biology" and involves studying a plant's strategy for existence in winter by observing it regularly. The class flow is as following: (1) Students understand the theme and choose a plant to observe. (2) They observe the plant regularly by using a digital camera and submit articles containing these observations to CoCoFolio. (3) The teacher advises each student on their next activity or on the best way to describe their observations in articles posted on the Discussion Board. The students also give comments and advise on peer's observation articles. (4) They set up a hypothesis concerning the strategy for existence and do an experiment. (5) They make a report and give a short presentation. Figure 4(a) shows the CoCoFolio window containing a student's work. It is clear that the students were thinking deeply by discussing their work on the Discussion Board. Moreover, the teacher's comments were essential to help the student understanding.

(b) Mathematics class

This 8th-grade learning theme is "similarity" and involves making and answering each student's custom questions. The class flow is as following: (1) Students answer original questions from the teacher. (2) They make custom questions by changing part of the original questions and submit them to CoCoFolio. (3) They answer and correct each other's questions. (4) They classify all questions according to the contents. Figure 4(b) shows the CoCoFolio window containing a student's work. The student uploads questions and figures scanned by a scanner. Then, students' and teachers' comments and

questions are written up on the Discussion Board.

(c) Japanese class

This 7-9th-grade learning theme is "language expression" and involves enriching language expression by making "Haiku" poems with photos in relation to nature or social phenomena. (A "Haiku" is a Japanese poem of seventeen syllables in 5-7-5 form.) Figure 4(c) shows the CoCoFolio window containing a student's work.

5. Discussion

Through observation of some classes, questionnaires from about 90 students, and discussion with the teachers, we came to the following conclusions concerning the use of CoCoFolio.

- Teachers can provide coaching and students can study anytime, anywhere.

Teachers could coach all students separately with CoCoFolio in non-class time. To coach each student separately took much time, but teachers were satisfied with teaching in a "distant face-to-face" style. On the other hand, about two thirds of students accessed the server from their home. Although this is very convenient, it caused a problem due to differences in home-computer environments of different students.

- Teachers can modify and comment on students' creations and works directly by using CoCoBoard.

In particular, in the case of art and design education like MANGA University, teachers need to modify and comment on students' works directly by using CoCoBoard. CoCoFolio is applicable to several other types of art and design education, such as fashion or industrial design as well as storyboard and GUI design for software on the web. Moreover, it can be used for collaborative design work by distant creators.

- Students can reflect on their learning by interacting with peers actively.

BEST COPY AVAILABLE

Eighty nine percent of students answered that they could reflect on their learning by viewing their peers' learning histories and by discussing their work on the Discussion Board. Many students wrote that they could try various ways of thinking about the same theme.

- Both students and teachers found CoCoFolio to use very easy.

Ninety seven percent of students answered that they could operate the system easily. Teachers could also use it on a browser, without having any technical knowledge, and make original classes.

- Students' motivation to learn is improved.

The Oizumi students had more fun studying and thinking more deeply than learning all together as a group with textbooks. Students' motivation to learn was improved by sharing learning results and comments from peers.

- CoCoFolio shares coaching comments with other teachers.

Informative comments provide other teachers with useful information; therefore, CoCoFolio also functions as a teaching portfolio.

- Submitted work is accumulated as learning materials for junior students in the school.

Contents in CoCoFolio can be used as learning materials or references for junior students. For example, questions made in the mathematics class make good learning materials for the next year. In addition, teachers can assess learning results by comparing them with those of the previous year.

- Discussion Board helps students to exchange opinions naturally.

Ninety one percent of students answered that they could write their comments interactively. CoCoFolio was really effective for exchanging opinions in their own class and between different classes in school. It will help discussion between different school years, for example, when students teach juniors in the same school.

6. Summary

We have developed and experimentally applied an electronic portfolio tool, called CoCoFolio, for enriching students learning. In two test application examples - at Kyoto Seika University and Oizumi Junior High School - CoCoFolio supports a series of expression activities: expression, sharing, peer-review, coaching, and reflection.

To encourage students to perform these activities, collaboration between students or between students and teachers is essential; therefore, we have developed a multi-layered drawing tool and a Discussion Board. Responding to peers' comments and teachers' coaching, Students can formulate new questions and advance their learning. At the same time, they can understand their peers 'different ways of thinking and improve their learning processes.

STUDENTS' READINESS FOR ON-LINE DISTANCE EDUCATION IN SLOVENIA

Viktorija Sulcic, M.A. and Dušan Lesjak, Ph.D.

University of Maribor, Maribor, Slovenia

Vika.Sulcic@uni-mb.si, Dusan.Lesjak@uni-mb.si

Abstract

Presence and expansion of on-line distance education (DE) are one of the characteristics of the information society by which we can estimate the level of its development. We witnessed many changes in Slovenia in the last decade, so we were interested in acceptability (and readiness) of Slovene students for on-line DE, especially because the Internet has so successfully penetrated into the Slovene society.

Keywords: on-line distance education, high education, Slovenia

Introduction

Lately, knowledge has been given increasing importance, yet more and more knowledge gained at schools quickly becomes out-of-date and therefore it must be updated. The act of "updating" the existing knowledge is mostly done by the active part of the population, which can hardly afford to leave their work and begin to study. Nevertheless, in the last decade, various forms of education have been developed, which help to solve this problem. One of them is on-line distance education (DE).

On-line DE belongs to the phenomena of the information society, which – with regard to its wide use – can indicate the development of a country (indicator of development by RIS (1999)). It is therefore likely that Slovenia will follow developed countries and that the introduction and usage of on-line DE is inevitable.

In the higher education in Slovenia only the Faculty of Economics, University of Ljubljana (http://www.ef.uni-lj.si) and Doba Maribor (http://www.doba.si) performed DE. DE at the Faculty of Economics is offered in traditional way with one exception, the on-line materials for a course on European Economic Statistics (http://www-lt.fe.uni-lj.si). The second institution, Doba, offers on-line DE supported by WebCT educational environment. On-line DE at Doba started in September 2000 with 35 enrolled students and in this academic year (2001/2002) they have additional 204 students.

On-line DE is being introduced at Faculty of Economics and Business (FEB), University of Maribor, too for an e-business course (http://www.uni-mb.si/~epfpodin) within which an experiment about students acceptability of on-line DE was conducted.

Readiness for On-line DE (an Experiment)

Participants of the Experiment

In spring 2001, an experiment with on-line materials instead of regular lectures for e-business course was conducted in which two groups of 20 students participated (experimental and control group). The control

970

group attended classical lectures, the other one studied with on-line materials (http://epf-se.uni-mb.si/e-gradivo/eb-index.htm).

After the experiment students used a questionnaire, composed of two sets of questions:

- With the first set of questions the participants of the experiment were asked about their IT attitude, usage of forum, on-line materials and obtained knowledge and
- With the second set of questions we estimated and evaluated their acceptability for on-line DE.

Students characteristics and their IT attitude

In Table 1, statistically significant correlation between student characteristics and their IT attitude are shown.

	Characteristics and attitude of students	**2.**	**3.**	**4.**	**5.**	**6.**	**8.**
1.	Gender						
2.	Motivation for studies						
3.	Average grade						
4.	Attitude toward IT						
5.	PC usage (subjective)			0.47**			
6.	PC usage (objective)						
7.	IT usage			0.52**	0.59**		
8.	Attitude toward lectures supported by IT	0.36*	0.45**	0.44**			
9.	Attitude toward lectures supported by AV			0.40*		0.39*	-0.45**

**p < .01 (2-tailed), *p <.05 (2-tailed)

Table 1: Significant correlation of student characteristics and their IT attitude

Among participants exists a positive correlation between the assessment of PC usage and their attitude towards IT (0.47), which shows that students with a more agreeable attitude towards IT also think highly about their ability regarding computer usage. Such users use IT actively (correlation with the variable attitude towards IT: 0.52 and correlation with the variable PC usage estimation: 0.59).

Interestingly, highly motivated students showed a keen interest for the use of IT (0.36). The same holds true for students who think highly about studies going on at EPF (0.45), as well as students who have a keener attitude towards IT (0.44).

In Table 2, regression analysis regarding the dependence of IT attraction to lectures on the independent variables from Table 1 is shown.

Included variable	B	t	Sig.
Average grade	0.162	2.463	0.020
IT attitude	0.119	2.420	0.022
F=7.415 Sig. 0.002; adj R^2=0.286			
Excluded variables: study motivation			

Table 2: Dependence of IT attraction to lectures on the independent variables

The analysis shows that IT mainly attracts students with higher average grades, as well as students who are in favour of IT, which is somehow understandable. We can easily assert that computer literacy leads to a more positive relationship towards IT supported teaching, and consequently, towards a better class participation.

Videotaped lectures were thought highly of by students who were a part of the experimental group (-0.44), who thought highly of IT (0.40) and who placed themselves in the group of serious PC users (0.39).

On-line materials

All participants of the experimental group found their participation in the experiment highly interesting, they wished they could use e-materials as a supplement for their lectures, and they expressed a belief that such materials should have been available for other subjects.

Opinion about usage of on-line materials	Control group	Experimental group
Attraction of on-line materials	81.2%	100%
On-line materials can complement lectures	87.5%	100%
On-line materials need to be used in other subjects	75.0%	100%

Table 3: Usage of on-line materials

As we can see in Table 1, students preferred the usage of on-line materials to traditional teaching.

The biggest obstacle for the use of e-materials through the Internet is high cost. If the costs of e-materials for the Internet usage were lower, 46.7% of students in the control group and 58.8% of students of the experimental group would use them.

Quality of on-line materials

Quality of materials for DE is essential. Quality elements of software evaluated by ISO 9126 standard, which determines 6 characteristics of software, are: functionality, reliability, usability, efficiency, maintainability and portability (ESSI-SCOPE 2001).

Standard does not prescribe the meaning of individual characteristics or the metrics for their assessment, because the meaning and assessment are connected with the purpose of software (ibid.). Therefore, the assessment of quality was left to software users, and was carried out by means of a two-level model. On the first level, students assessed individual components of the used e-materials or activities, which were connected with the usage of e-materials in the experiment. Because not all characteristics are equally important and because the importance of individual characteristics is by nature subjective, we - in order to assess the importance of a characteristics, typical for e-materials in general - decided to include students, who sorted the ten characteristics from 1 to 10, placing on the first place what they considered the most important characteristics and on the tenth place what they believed to be of least importance. On the basis of this information we calculated relative weights (ponder) for each characteristic in the assessment model (Table 4).

	Components of evaluation model	M	Ponder	evaluation
1.	Ease of use	7.67	0.15	1.15
2.	Graphical design	8.24	0.11	0.91
3.	Text understanding	8.21	0.15	1.23
4.	Interactivity	8.16	0.09	0.73
5.	Readability of texts	8.19	0.14	1.15
6.	Links to similar areas	7.81	0.08	0.62
7.	Links to web pages of the course	7.81	0.07	0.55
8.	Entertaining content	7.28	0.06	0.44
9.	Clear learning objectives	8.18	0.10	0.82
10.	Cited literature	6.52	0.05	0.33
	Total		**1.00**	**7.93**

Table 4: Evaluation model of quality of on-line materials

E-materials were assessed as very good, as they were assessed with 7.93 on the scale 1 to 10.

Evaluation of gained knowledge

Gained knowledge was assessed by means of a knowledge test that comprised of 32 questions, which were used to check student's ability of recognising the materials dealt with.

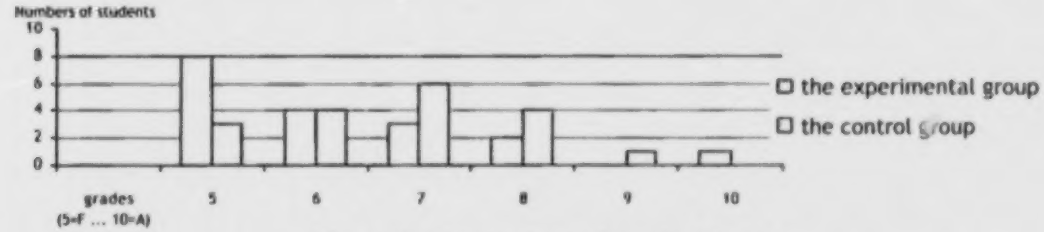

Figure 1: Comparison of results of tests

It can be seen that the members of the control group proved to be much more successful than the members of the experimental group. More than one third of the students of the latter group did not manage to remember enough in one hour of learning to gain a positive mark. Taking into account the fact that the contents of lectures was the same in e-materials and in ordinary lectures, poor results can be explained only by believing that the students of the experimental group did not pay enough attention to learning objectives set at the beginning of the materials. Quite obviously, an ordinary lecture, assessed pretty highly by the participants (M=8.7; on a scale 1=poor to 10=excellent), is still very important for students. The classical lecture was supplemented by practical cases and learning objectives were explicitly given, which probably contributed towards better recall of basic terms.

When we merged the questionnaire of the selected group with the tests, which assessed knowledge we wanted to find out if the result of the test is statistically correlated with any other variable. The results of regression analysis are shown in Table 5.

Included variables	B	t	Sig.
Usage of Internet	6.982	2.614	0.014
Gender	-3.092	-2.424	0.022
F=6.404 Sig. 0.005; adj R^2=0.252			
Excluded variables: motivation, attitude toward IT			

Table 5: Dependence of the students' success in tests

The regression analysis shows that better results were reached by male students and students who used the Internet and e-mail. This at the same time proves the hypothesis that computer-literate students are likely to be more successful in on-line distance education.

We have also proved the hypothesis that the experiment will be interesting for the chosen group, as all members of the experimental group expressed keen interest for the experiment, as well as 81.2% of student in the controlled group.

Readiness for DE

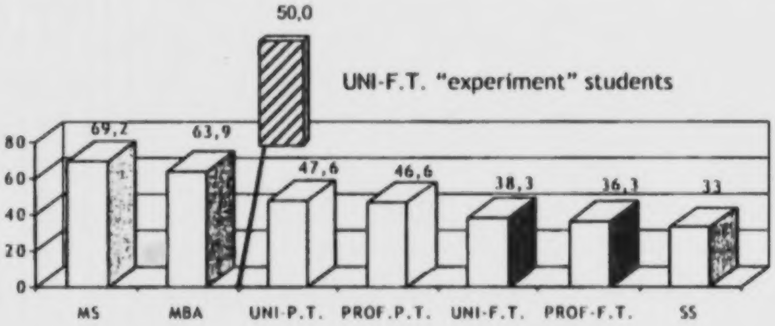
The readiness was evaluated on the basis of the model of acceptability of on-line DE, which includes the following items – participants' characteristics (and their relative weights):

- Motivation (20%),
- Students' connection necessity (8%),
- Possibilities for IT using and relationship to IT (32%),
- Abilities for IT using (30%),
- Usage of e-services (10%).

The students estimated their study motivation and some other characteristics on a five-degree scale. The average value, corrected with standard deviation, was included in the model. The same method was used for assessing their relationship and experience with IT. The estimations of DE readiness, shown in Figure

2, was calculated through corrected average values for some variables and percents of variables and their relative weights for other variables.

We also tried to assess FEB students' readiness for DE in general. Thus 652 students from various FEB programmes (different undergraduate and postgraduate, full time and part time programmes) were inquired and gathered data was analyzed with the model of Internet based DE acceptability. The results are shown in Figure 2, which shows that students in both postgraduate programmes point at a higher DE readiness, which is a consequence of higher motivation, longer learning experience and higher computer literacy.



Legend: MS – postgraduate master of science study; MBA – postgraduate MBA study; UNI – university (4 year) program; PROF – professional (3 year) program, P.T. – part-time study, F.T. – full-time study; SS – secondary school

Figure 2: FEB student's readiness for DE (11)

Based on the gathered data from the students who participated in the experiment and the model of readiness for DE, their DE readiness was estimated, too. The estimated value 50 is higher compared to the readiness estimated for FEB full-time university program students (38.3) (11). Higher acceptability of DE can be explained with their higher computer literacy and with better IT experience in education process obtained by using various on-line materials from the e-business course's web site (http://www.uni-mb.si/~epfpodin).

The estimation of readiness proves that higher computer literacy raise the readiness for DE, supported by IT. Improved computer literacy leads to better chances for the introduction of IT, be it for business purposes or the advancement of e-services.

Conclusion

Major findings of the experiment and its research are:

- The first step toward DE at the Faculty of Economics and Business (FEB) in Maribor has been done (for an e-business course).
- The students prefer on-line materials and DE is generally acceptable especially among postgraduate students so the possibilities for on-line DE at FEB exist and FEB needs to take the necessary steps to exploit this opportunity.

- Keen interest of the participants in the experiment group for the introduction of IT in education is connected with the fact that students can only express enthusiasm about something they have experienced and used. DE supported by IT will begin to flourish only if (and as soon as) IT has been included in teaching properly.

CMI Theory and Practice: Historical Roots of Learning Management Systems

Michael Szabo, Ph.D. and Ken Flesher, President, Basecorp Learning Systems
University of Alberta

Edmonton AB

Abstract: Learning Management Systems (LMS) represent a rapidly expanding domain of e-learning which are touted to bring great efficiencies and effectiveness to organizations through growth and training of employees. Their presence is made possible by recent gains in instructional technology of power, speed, and accessibility, enhanced by the demise of the limitations of microcomputers of the 1980s. There is little current LMS research to support the marketing claims made by system vendors, with respect to either organizational or individual change and effectiveness. LMSs in fact have a rich history in theory and practice, derived from numerous projects and studies completed during the days BC (before microcomputers), when mainframes roamed the earth, devouring vast sums of money and programming expertise. This paper will examine key elements of the seminal history of computer-managed instruction (CMI), including developmental writings, theoretical underpinnings, and applications in various fields. It is the hope that lessons will be drawn from this work which may inform those engaged in reinventing the wheel.

LMS and CMI

Learning management systems are computer based database and presentation systems which manage the entire instructional program and learning progress of employees with respect to the competencies specified by the goals and objectives of an organization. Computer managed instruction systems, from which LMSs are derived, manage the learning program of individuals in terms of 1) diagnostic assessment of performance relative to some standards and 2) prescriptive assignment of learning resources relevant to those standards. See Figure 1 for a generalized CMI system.

Historically there are two major defining sources for CMI systems. The first is a paper by Baker (1981) in which the functional specifications of a CMI system are laid out. The second is the development of a numerous sophisticated CMI systems, one of which was at the time the most heavily used software package in the Control Data Education Company's repertoire of extensive courseware.

Baker (1981), at the dawn of the microcomputer age, addressed the question of integrating computer based instruction (CBI) into an enduring fabric of educational systems and argued that CMI is the needed tool because "...modern instructional strategies are becoming more complex and thus harder to manage from an instructional and administrative point of view[s]" (p.23). He outlined a system which would address the instructionally-related functions of: 1) data collection, 2) individualized diagnosis and prescription, 3) performance monitoring, 4) scheduling, 5) resource allocation and 6) reporting. In addition, his specifications included computer-related functions of: 1) man-machine interface, 2) database management, 3) and system-generation. His analysis further specified the data requirements as: 1) assessment, 2) diagnostic, 3) prescription, 4) resource and 5) curriculum evaluation. Finally, he specified the hardware requirements in terms of the dominant hardware of the day, the mainframe with dumb terminals and optical scanning devices attached.

Meanwhile, Michael Allen, creator of Authorware, designed a CMI system for use with PLATO, which was at the time a mainframe system entirely devoted to the delivery of instruction and training. Called PLATO Learning Management (PLM), this system was designed to work with most curricula and was employed to manage the massive amount of courseware produced by the CDC Education Corporation. PLM was also available for PLATO clients to integrate with their custom courseware programs.

Other organizations and individuals developed CMI systems which had varying degrees of impact on their organizations. A CMI system was custom-developed for the University of Illinois PLATO system, which was the original system that became the basis for the CDC PLATO system. The U.S. Air Force developed an optical-scan based CMI system (Automated Instructional Systems) for training of personnel who supported military aircraft. This system evolved over the years into one currently used to train fighter pilots. Several of these systems used by the military were reviewed by Tennyson and Park (1984).

Learning theory

Today's LMS vendors generally do not elaborate the learning theory basis upon which their systems operate, suggesting the lack of such background. What is the learning theory basis of early CMI systems? Since most CMI mainframe systems originated in higher education, it is not surprising they embodied theories of how people learn. Here is a brief summary of five theory-based strategies which have influenced CMI: metacognition, individual responsibility, error correction in human judgment, individualized instruction and deep cognitive processing. Note that these theories may have been modified or superceded since their use as a basis for CMI.

Metacognition

> Metacognitive experiences involve the use of metacognitive strategies or metacognitive regulation (Brown, 1987). Metacognitive strategies are sequential processes that one uses to control cognitive activities, and to ensure that a cognitive goal (e.g., understanding a text) has been met. These processes help to regulate and oversee learning, and consist of planning and monitoring cognitive activities, as well as checking the outcomes of those activities (Livingston, 1997).
>
> For example, after reading a paragraph in a text a learner may question herself about the concepts discussed in the paragraph. Her cognitive goal is to understand the text. Self-questioning is a common metacognitive comprehension monitoring strategy. If she finds that she cannot answer her own questions, or that she does not understand the material discussed, she must then determine what needs to be done to ensure that she meets the cognitive goal of understanding the text. She may decide to go back and re-read the paragraph with the goal of being able to answer the questions she had generated. If, after re-reading through the text she can now answer the questions, she may determine that she understands the material (Livingston, 1997).

CMI systems claim to supplement the self-metacognition strategies with objective, second party information. For example Szabo & Forsyth (1994) found that exposure to a CMI system while studying mathematics initially resulted in increased learning but the effect leveled off over time, leading to the hypothesis that CMI provides a metacognitive model which learners adapted to sharpen their study skills through a better understanding of their own learning approaches.

Individual Responsibility

Individual responsibility theory (IRT), individual responsibility for success or failure to learn, comes from research on motivation (Wittrock, 1979) which largely draws on attribution theory and locus of control. In locus of control, achievement has been increased by teaching learners to believe they can influence their destiny in school by their efforts (deCharms, 1972). Instructors and learners are taught they are the origins—people who cause their behavior—rather than pawns or people largely under control of their environment. The latter is often accompanied by feels of helplessness which can interfere with learning.

Attribution theory (Weiner, 1976) is closely related and posits that success and failures in one's life is largely attributable to luck or task difficulty which are variable or stable external causes. Quite often one's attribution beliefs stem not from the school performance results which they attain, but from the manner in which those results are communicated by the instructor and the social structure of the classroom.

One implication for instruction is to provide information about personal levels of performance in an objective and non-threatening environment with the belief that such information can stimulate self-corrective action. Thus, CMI systems have been used to function in an individualized fashion, providing confidential feedback to individuals on their individual pattern of meeting competencies. In addition, they function in an objective fashion, such that learners receive feedback with respect to what they have learned rather than relative to their standing in some comparison group. Such assessments are called criterion-referenced or norm-referenced, respectively, and much has been written about them in the measurement and evaluation literature. Finally, most CMI systems provide paths to learning resources (diagnostics) and the opportunity to return to the assessment portion to improve their performance (Figure 1); this implies some control over the person's environment.

Error Correction in Human Judgment

This theory is based on the observation that people tend to overestimate their own strengths and underestimate their weaknesses, in short, to be poor judges of their own abilities. When learners are placed in a self-paced learning environment, they must often judge whether they have successfully learned the content before they proceed to the next module, which may have the previous one as prerequisite. They can succumb to either prematurely proceeding to the next module, inadequately prepared, or unnecessarily return to the current module and study excessively. Both strategies are at the best inefficient and perhaps ineffective.

This problem is addressed in CMI by giving learners another source of objective information regarding their own progress. When a student finishes a module and has to decide whether to return or go on to the next module, a CMI system allows the learner to complete an objective assessment of his or her level of performance on the objectives of the module. The instantaneous feedback embedded in the exercise provides an unbiased assessment which can be used to fine tune the decision to proceed or not.

Tennyson (1981) developed such a CMI system which he referred to as an advisement system (Advice by Computer), to provide objective advice to learners to use to check their performance decisions. He found that his advisement system resulted in both increased achievement and increased ability to monitor one's own performance.

Individualized Instruction

The theoretical basis of this approach is that individual performance exhibits great variability within a group of learners. For example, the rate at which a defined group of individuals learn typically varies by a ratio of 5 to 1, suggesting the need for self-pacing. Entering knowledge of individuals with respect to content being taught varies significantly, as revealed by course pretest data. This is particularly true of adults who have had wide ranges of experiences and learning compared with adolescent learners. However, classroom-based instructional strategies, to be administered efficiently, require that all learners cover the same material in the class at the same time and same pace. This leads to inefficiencies and reduced motivation to learn.

Competency-based learning/mastery imply a repeated cycle of instruction and testing until competencies have been met. The iterative nature of the computer offers significant potential to accommodate this cycle through its ability to administer exams with little or no instructor intervention and to clerically process the data and present the performance results in a summary form to the instructor.

Diagnostic and Prescriptive Model for Individualized Instruction

Figure 1

Figure 1: Diagnostic and prescriptive model for individualized instruction via CMI.

BEST COPY AVAILABLE

CMI systems can support individualization in several ways. First, each student can be tested over a unique set of competencies as tailored to that person's job classification and performance. The testing can be done through computer-administered instruments, evaluation by expert judges, or both. The study assignments resulting from deficiencies are tailored precisely to those deficiencies. Generally CMI systems accommodate individual differences by allowing learners to: 1) proceed through instruction at a comfortable rate of learning, 2) skip those competencies where they can demonstrate mastery, thus greatly reducing time spent in instruction, 3) start at any point in the instructional sequence, and 4) obtain specific performance indicators and suggestions for what to study to alleviate any performance deficiencies (See Figure 1). Furthermore, this data is tracked, stored and can be recalled and reported for progress and due diligence reports for the individual, training unit, organization and certification agency.

CMI can also accommodate performance competencies requiring demonstration of a performance skill. Once evaluated by a qualified trainer or supervisor, the results can be entered into the system to maintain a comprehensive tracking and reporting system.

A system based on PLATO Learning Management was implemented in the Edmonton Police Department during the 1980s. Officers were able to skip individual units of instruction if their performance on a pretest indicated mastery. A follow up study (Szabo, 1987) indicated the system was instrumental in increasing paper and pencil achievement, on the job performance and reducing training time by 25 percent, resulting in a savings of approximately $350,000 over a 5 year period.

A massive use of PLM involved the basic skills adult literacy curricula (grades 3-8 and 9-10). Pretests indicate what grade and month level a learner should begin in the basic skills of mathematics, science, social studies, reading and English. Student's programs were individually monitored and extensive feedback provided to guide both learners and instructors. Sample reports from this program can be found in Szabo (1994).

Deep Cognitive Processing

This approach evolves from the information processing theory of learning that says that learning is affected by the structure of the mind as perceived to be like an information processing system. A simplistic view reveals its components to be: 1) a system to perceive the external world, 2) short term memory (STM) in which to temporarily store the information which successfully navigates the perceptual system, 3) a long term memory storage system (LTM) and 4) a working memory (WM) where information from STM and LTM are mixed in order to update LTM.

A known problem is that STM is severely limited in the amount of information it can hold (5 plus or minus 2 'bits' of information), and it regularly dumps information which cannot be processed in wm sufficiently to become part of ltm. To solve this problem, theorists have proposed that the process of dumping information into stm be regularly and systematically interrupted and interspersed with activities which stimulate wm. This 'forces' the processing of information by the learner to minimize its loss from stm before it can be integrated into ltm.

An example of this concept is as follows. Instead of assigning 100 pages of reading material, it is assigned in 10 page blocks, or something equivalent, depending on the density of information. After reading each 10 page block, the learner signs on to a CMI program which provides a diagnostic and prescriptive assessment of the information to be learned from those ten pages. In other words, the "dumping" of information into the stm is interrupted by cognitive processing activities, which should enhance learning. Further cognitive processing is provided by arranging the feedback such that the location of the answers are provided rather than the answers themselves. This requires additional cognitive processing. Finally, if the questions are pitched at a high cognitive level, it is argued that deep cognitive processing occurs and learning is improved.

Anderson et. al., (1975) developed a computer assisted study management system (CAISMS) based on the deep cognitive processing theory for use in an economics course. A well-controlled experimental research study compared learners who used CAISMS with those who didn't. Learners in the treatment group read study assignments and immediately completed on-line tests to assess their learning. Successful learning allowed a student to proceed through the syllabus, while unsuccessful learning required continued study of material already covered with retest opportunities.

Results from this study indicated that learners using CAISMS scored significantly higher on all course exams. One student's anecdotal comment is worth noting: "I really think CAISMS helped me a lot in this course, if not for anything else, it made me study regularly and be sure I got the right things out of what I read" (p. 8). Attitudes toward the course and method, as measured in the Anderson et al. study were significantly higher for the CAISMS learners. Attitude scores for learners was improved through the use of CAISMS for large but not for small classes. CAISMS had no overall effect on course completion rate.

A Brief History of CMI Application and Research

Several large-scale projects on managing and individualizing instruction in the 1960s and 1970s found the computer to be valuable in managing instruction: Program for Learning in Accordance with Needs (Flanagan, 1969); Individually Prescribed Instruction (Cooley & Glaser, 1969); and Instructional Management System (Silberman, 1968).

Dozens of mainframe CMI applications have been made over the years with agencies such as United Airlines pilot training, Naval personnel training, and educational courseware at all levels from grade 3 through adult basic education.

A CMI program was developed for a nursing course at the University of Alberta. A controlled study Kot, Skillen & Wales (1986) showed that the CMI group and non-CMI group had equivalent achievement scores and learning times. The instructors in the non-CMI group spent twice as much time per student than the instructors in the CMI group. At the same institution, Boblin & Gibson (1986) reported learners in the CMI class achieved higher marks for all unit tests and final course mark. Because of the lower rate of attrition in the CMI course, the authors raise the possibility that the course with CMI would not function well as the 'first screen' for learners in the program.

In terms of development costs, Fahy (personal correspondence, November 1987) indicated that a CMI application, using the existing PLM system and existing learning resources could be developed in 5 minutes per test item. Szabo & Estes (1978) compared costs of developing computer managed and computer assisted instruction in nursing courses and concluded that the former takes one-fourth the development time compared with the latter.

Szabo & Montgomerie (1992) made the following conclusions a decade ago.

> Much of the research on CBT includes components of CMI, so it is difficult to isolate the specific contribution made by CMI to the effectiveness of the instruction, attitudes towards computers, etc...The very strong impression gained from a review of the studies reported here is that CMI has shown to be efficient, effective and relatively easy to develop compared with other forms of mediated instruction. Experience indicates that CMI can be implemented by instructors, working alone or in teams...A comment often made within developmental teams is that one of the major benefits is the logical re-thinking of a course or curriculum required when implementing CMI...CMI has been shown to be useful in the context of existing courses (e.g., Anderson, et al, 1975; Boblin & Gibson, 1986) as well as in brand new courses (Szabo & Estes, 1978). It has also been used as mainline instruction or as supplementary instruction, (the latter required or optional). CMI has been successfully applied over a wide range of content areas, ranging from nursing to special education to pilot training (p. 127-130).

Two final observations arise from the 1992 article. The first "Although not systematically reported here, there is a rapid proliferation of microcomputer based CMI applications and programs as people begin to apply the microcomputer to the management of student learning" (p. 130) did not happen as rapidly as predicted. It apparently had to wait for the advent of a system which includes worldwide computer networks, massive database storage facilities, creation of CMI software, new programming languages and the Internet.

The second observation "The only bit of advice we would offer here is for aspiring developers to carefully examine the features of the most outstanding mainframe-based CMI systems and avoid reinvention of the CMI wheel (p. 130) is still the recommendation of choice, with the proviso that the focus be LMSs rather than CMI.

Recent Examples

New York-based Vuepoint Corporation worked with Toyota to train its 88,000 Toyota and Lexus dealers and corporate associates in the United States. Vuepoint will design and implement an enterprise-wide e-learning system that Toyota projects will pay for itself within 24 months and realize an estimated net savings of $11.9 million over five years. Vuepoint Learning System 3.0 will provide the base training infrastructure for University of Toyota and allow it to consolidate numerous systems. The platform integrates LCMS, LMS, authoring, and virtual collaboration. Consultant Sapient Corporation is partnering on the implementation. (Learning Circuits Express, 2002).

The Thomson Corporation is celebrating a new multi-year contract to provide e-learning courses to General Motors employees via General Motors University. Thomson's Cardean University, which collaborates with leading business schools, will expand its relationship with GM U to provide an e-MBA program along with custom courses for GM's automotive business. GM already uses some of Cardean's online executive and management development courses. The agreement to expand the full suite of Cardean products to global GM employees follows the successful integration initiated last April of the GMU/Cardean HR Skills for Success program. (Learning Circuits Express, 2002).

Ceridian Canada, Canada's leading payroll management company, has selected San Francisco-based Ninth House to supply online management training for a performance improvement initiative that will focus on managers and customer service. Ninth House courses, simulations, and Instant Advice tool are being rolled out to Ceridian managers throughout the country as part of a program to strengthen Ceridian's management team across a dispersed workforce. (Learning Circuits Express, 2002).

Delta Air Lines has selected Pathlore's LMS to plan, deliver, and manage its training programs. The initiative debuts in May with an enterprise-wide simulation workshop on business literacy. Delta also will use Pathlore's LMS to deploy blended-learning programs. Other training initiatives will include skills management, corporate compliance courseware, a content repository, and professional development. (Learning Circuits Express, 2002).

Summary

Learning management systems have emerged from the ashes of early mainframe-based CMI systems, thanks to the LAN, WAN, Intranet and Internet, driven by large databases in servers. Touted for their ROI, often without substantiation, LMSs possess a rich heritage in learning theory, which has largely been lost or understated by commercial ventures intent on developing systems to manage the corporate training program and hopefully provide increased organizational efficiency. Several benefits have been attributed to LMS. It has been claimed that they can:

1. reduce costs through decreased training redundancy and reduced operational errors and down-time,
2. maximize efficiency through integrating into one system safety issues, operating procedures, maintenance packages, environmental standards, and job reference. This one systems makes auditing easier and less expensive, and
3. leverage existing resources through including established policies and procedures; utilizing existing training material and links to "off-the-shelf" commercial computer-based courseware.

A fair question to ask is What evidence is there to support these claims? Several research questions arise from this exercise.

Is learning (attainment of knowledge, skill and attitudinal competencies) enhanced through the use of a Learning Management System?

Does the addition of a Learning Management System impact the structure or culture of an organization? For example, does it result better alignment between corporate mission, goals, and employee competencies?

Can a Learning Management System be expected to generate a ROI? If so, what magnitude might be expected?

Is there value in reviewing recent developments in learning theory (since the days of the original CMI) to ascertain the appropriateness of LMS' applications?

Students Develop Real-World Web and Pervasive Computing Systems

Charles C. Tappert
School of Computer Science and Information Systems
Pace University, USA, ctappert@pace.edu

Abstract: In the academic year 2001-2, Pace University CSIS students developed real-world Web and pervasive computing systems for actual customers. We describe the general use of team projects in CSIS at Pace University, the real-world projects from this academic year, the benefits of including real-world projects in the curriculum, and their cost in terms of the instructor load and the project development infrastructure. We found that the benefits of our method of structuring and conducting the real-world projects far outweigh the cost of providing them. The projects provide valuable systems for the customers, allow the students to develop technical and value skills, foster interdisciplinary collaboration, encourage student involvement in the university and local communities, support student and faculty research, enhance relationships between the university and local technology companies, and increase national recognition of the university.

Introduction

In the academic year 2001-2, the School of Computer Science and Information Systems (CSIS) at Pace University used real-world Web and pervasive computing systems as team projects in a two-course capstone sequence in Software Engineering, and in an elective course in Pervasive Computing Systems, in the Master of Science in Computer Science program. Although the students in both these courses develop systems for actual customers, the emphasis of the project work in these two courses is somewhat different. In the software engineering sequence, the customers are referred to as clients. The clients are the source of the project requirements, and the teams focus on developing systems that meet the real needs of the clients. In the pervasive computing course, student invention teams, called E-Teams, the "E" standing for "entrepreneurship," work with customers to build innovative systems that use pervasive computing techniques and that demonstrate the feasibility of potential commercial products. In that course, the customers are referred to as mentors since they are typically the knowledge sources for the systems. In this paper, the term "customer" will be used for both client and mentor in describing 18 student projects.

Developing real-world systems for real customers provides an excellent setting for teaching students team and value skills by following a human-centered development process. While it is clear that students of computing must learn technical skills, current thinking is that they must also learn "value skills" of how to interact with customers to provide them with the promised value-producing systems. Six categories of value skills are described in (Denning & Dunham 2001): coordination (of requests, offers, promises, etc.); customer relations; commitment management; teamwork; lifelong learning; and business and entrepreneurship skills. Dertouzos (2001) also makes a strong case for human-centered computing in which technology adapts to people rather than the other way around.

The real-world projects provide valuable systems for the customers, allow the students to develop technical and value skills, utilize student-centered learning, foster interdisciplinary collaboration, encourage student involvement in the university and local communities, support student and faculty research, enhance relationships between the university and local technology companies, and increase national recognition of the university.

The following sections describe the general use of team projects in CSIS at Pace University, the real-world projects from the 2001-2 academic year, the benefits of including real-world projects in the CSIS curriculum, their cost in terms of the instructor load and the project development infrastructure, and conclusions.

Team Projects in CSIS at Pace University

The Computer Science department at Pace University has frequently used team projects to provide students with the educational experience of working together in teams, similar to what is done in industry, in order to design, build, and test computer information systems. For several years prior to 2001-2 the software engineering course sequence had each student team develop as its project an "Order Processing System." For these "canned" projects the instructor has played a dual role, acting as both project manager and customer.

A project team typically consists of 4 to 5 students: an Architect-Designer, one or two Implementers, a Quality Officer, and a team Coordinator-Liaison (Pressman 2001). Ideally, teams should meet once a week in addition to project work time. Team members should work together and coordinate activities as a unit – for example, communication, including e-mail, between the team and the customer should be done as a group or should be coordinated by the team leader. In recent years, Java has been the preferred language at Pace University for projects that require programming. Although the requirements for the projects come from the customers, the course instructor is the "boss," or "Chief Executive Officer," of the project teams – that is, the person who makes all the major decisions and adjudicates personnel problems.

Real-World Projects in 2001-2 in CSIS at Pace University

Using real-world projects with real customers is not new; for example, the University of Southern California's Center for Software Engineering (USC CSE Website 2002) has been doing this for years in their capstone two-semester software engineering sequence. However, we believe that our program is unique because it focuses on value skills, serves the community, and is organized on a large scale with supporting project infrastructure.

Eighteen projects were completed during the 2001-2 academic year (Table 1). Ten were Web interfaces to backend databases, four were medical applications, three concerned VoiceXML or InkXML, and one was a cluster and grid computing system. The customers were from various Pace University schools/departments and from several outside organizations. The university schools/departments included the School of CSIS; the Lienhard School of Nursing; the Lubin School of Business; the Office of Planning, Assessment, Research, and Academic Support; the Department of Information Technology (DoIT); and the Doctor of Professional Studies (DPS) in Computing program. The outside organizations included Northern Westchester Hospital, IBM Research, the Psychology Department at SUNY New Paltz, and the Fulbright scholarship program. The table column on scripting/database software will be discussed later in the section on project development infrastructure.

	Project	**Customer Affiliation**	**Scripting/database software**
1	Online Course Survey System	Planning & Assessment/Pace	ASP/Microsoft Access
2	Project Group Assignment System	CSIS/Pace	Cold Fusion/Microsoft Access
3	Test Item Reliability Analyzer	CSIS/Pace	PHP/MySQL
4	Genealogy Web Application	CSIS/Pace	Cold Fusion /MySQL
5	Dean's Communication System	CSIS/Pace	Cold Fusion/Microsoft Access
6	PC Maintenance/Tracking System	CSIS/Pace	Cold Fusion/Microsoft Access
7	DPS External Website	DPS Program/Pace	PHP/MySQL
8	Experimental Handwriting System	CSIS/Pace	ASP/Microsoft Access
9	Rare Coin Grading System	DPS Program/Pace	ASP/Microsoft Access

12	NIS Wireless Extension	Nursing/Pace and DoIT/Pace	–
13	Emergency Pre-Hospital Care Communication System	Northern Westchester Hospital and Business/Pace	–
14	Medical Vital Sign Wearable	CSIS/Pace and IBM Research	–
15	VoiceXML App. Devel. Facility	CSIS/Pace and IBM Research	–
16	VoiceXML Applications	DoIT/Pace, CSIS/Pace, and Psychology/SUNY New Paltz	PHP/MySQL
17	Multimodal Voice/InkXML System	Fulbright Program and IBM	–
18	Cluster/Grid Computing System	CSIS/Pace and DoIT/Pace	–

Table 1: The eighteen Web and pervasive computing projects in 2001-2.

The student teams were required to write technical papers for possible publication describing their systems. Eight, referenced herein, were presented at this year's Mid-Atlantic Student Workshop on Programming Languages and Systems, and PDF versions are available from the workshop's Website (MASPLAS'02 Website 2002).

Web interface to backend database client/server systems

Ten of the eighteen systems consisted of a Web interface to a backend database using the client/server architecture. The simpler ones simply allowed users to enter information into the database and retrieved the data for appropriate viewing. The more complex ones performed calculations on the data, which in some cases was substantial.

The **Online Course Survey System** (Pethe, et al. 2002) was designed to automate Pace University's manual course-end survey system, in which students complete paper surveys to evaluate the courses they have taken. With the new system, students log in to take the survey through a Web interface, results are retained in a database, and survey statistics can be accessed from the Website. The system was tested by running in parallel both the old and the new survey systems on two large CSIS courses at the end of the spring semester. It was also used to obtain surveys for all online CSIS courses, courses for which it was previously not possible to obtain survey results, since the students in these classes do not physically attend class and therefore cannot be given a paper survey to fill out. These tests were successful and it is anticipated that the whole university will soon move to an online system.

The **Project Group Assignment System** (Doyle et al. 2002) is a Web-based system that creates teams (groups) for project work in industry or academia. This system addresses problems that arise in the usual, manual team-creation process, which can be tedious, time consuming, perceived as unfair, and may not get a good mix of expertise. In the automated system, the project managers enter the project information: project descriptions, suggested team size; customer information; and parameter weights for team candidates' project preferences, availability, geography, and experience. Potential team members complete an online survey to record their project preferences, preferred availability times and locations for team meetings, and their academic and/or professional experience. The project manager then executes a Java program that groups the candidates into teams, and team members and program managers can view the resulting teams through the Web interface. Since an exhaustive search for the optimal solution is not possible for more than a small number of projects, the algorithm uses a greedy search approach to obtain a near-optimal solution similar to a previous stand-alone program (Redmond 2001).

The **Test Item Reliability Analyzer** allows instructors to perform statistical analysis on multiple-answer tests. The measures provided by the system give the instructor greater insight into the relative preparedness of the students as well as the validity of individual test questions. The system computes five item (test question) measures: item difficulty (the percentage of students answering the item correctly), item variance (a measure of the variability of the student responses), item discrimination (a measure of the discrimination power of a test item), item correlation (a measure of the correlation between the item and the whole test), and item distraction (incorrect alternatives for a test item that are never chosen and should therefore be removed or replaced). It also computes an aggregate analysis indicator of overall test quality and accuracy. Such objective measures of the questions are valuable, since the things that separate good items from bad items are best not left to the subjective interpretation of the test constructor. The one similar system found (ITEMAL 2002) is proprietary to the University of Delaware, was never intended for public distribution, and is not very flexible or user-friendly. The new system successfully analyzed the quizzes used in the software engineering course and indicated where improvements can be made.

The **Genealogy Web Application** (Barbosa et al. 2002) is an example of developing a Web-based application that improves on an existing commercial product – the shrink-wrapped, stand-alone software application packages for the Microsoft Windows Operating System environment. With the stand-alone genealogy systems, usually one family member researches, inputs, and publishes his family tree and thereby undertake the tedious and never-ending task of updating and maintaining it, a particularly burdensome task for large family trees. In contrast, the Web-based application distributes this burden by allowing several family members to update and maintain their branch of the family tree and to do so remotely from anywhere through a Web interface. Furthermore, all family members can view the family tree information on the Web.

The **Dean's Communication System** assists the Dean of the School of CSIS in her communications with faculty, students, and others at Pace University. It consists of a database backend with both an external and an internal Web interface. The external "Communications from the Dean" site is accessible by all, and the internal one is accessible only by those having access permission. All communication items are stored in the database for tracking and for historical record keeping.

The **PC Maintenance/Tracking System** assists in the maintenance, support, and tracking of PCs in CSIS at Pace University. Information is captured when a PC is reported as having a problem or needing an upgrade (information such as the date, the PC ID, the PC's location, the nature of problem or upgrade), when the problem is fixed (what repairs were made), when software is installed (the software, the installer), when a PC is moved, etc.

The **DPS External Website** team developed a new Website for the Doctor of Professional Studies (DPS) in Computing program (Merritt et al. 2001). This site improves on the old site in terms of elegance, clarity, and ease of navigation. It has a backend database and a link to a back office interface that allows administrators without knowledge of HTML to change or update the look and content of the Website. The site also allows visitors to request information and to submit an application online.

An **Experimental Handwriting System** was developed to investigate the detection of handwriting forgery. The team collected handwriting samples from ten subjects who wrote a set of words in their natural style and attempted forgeries of the other nine subjects' handwriting. These handwriting samples were digitally scanned and stored in an image database. A Web-based quiz was developed to gather statistical data from users trying to distinguish between the original and the forged handwriting samples. Novices and certified document examiners (CDEs) were asked to take the online quiz. Although many students took the quiz as novices, only a few CDEs were willing to do so, and the results were inconclusive. The implications of this and similar studies may have bearing on the admissibility of handwriting testimony in U.S. courts. The database of handwriting samples was also used in a study of handwriting forgery detection by machine (Cha & Tappert 2002).

The **Rare Coin Grading System** (Bassett et al. 2002) was designed to automate the grading of rare coins. In the numismatic community today, the official grading of coins is accomplished by human inspection. This, by its very nature, lends itself to inconsistent results that can misrepresent the actual value of a coin by thousands of dollars; there is also the danger of misrepresentation for personal gain. The team obtained graded coins and created a database for storing their images. Then, they developed a Web interface to an educational quiz environment in which experts and novices can try their hand at grading the coins in the database. Finally, they developed a rudimentary machine grader by extracting three histograms (hue, saturation, and brightness) and an edge detection function from the digitally scanned color image of the coin to be graded, and assigning that coin the grade of the pre-graded coin that it most closely matched. Preliminary results of the machine process appear reasonable and indicate the promise of the approach.

The **User Verification System** (Baker et al. 2002) was developed to investigate combining several biometrics in order to develop a high-confidence user verification system. Such a subsystem can be embedded into any system that requires high security and can be developed using various combinations of different modalities; this project used four: face, fingerprint, handwriting, and voice. Each of the four verification systems involves techniques of pattern recognition to compare signal samples from the input device with those from the database, and each can result in type I (valid user rejected) and type II (invalid user accepted) errors. Combining these four different verification techniques should achieve a high level of confidence. Initial work on this problem focused primarily on face recognition and resulted in a database of digitized photos and preliminary studies of verification by face image.

Medical application systems

Four systems involved medical applications. The **Nurse Information System (NIS)** (Palmer et al. 2002) physical assessment application walks a student nurse through a physical assessment. A legacy system on a proprietary device running an obsolete operating system was ported to a Java 2 Micro Edition (J2ME) implementation. The application was completely redesigned and rewritten using object-oriented design techniques to create portable classes for reuse and for use in future applications. A small prototype was built and scaled up to a full application on Palm personal digital assistants (PDAs) running the PalmOS. A C++ conduit was also written to allow the prototype to transfer data from the Palm handheld devices to a PC for storage and further evaluation.

The same students who developed the above-described NIS in the software engineering course extended that system with an **NIS Wireless Extension** in the pervasive computing course. They provided the earlier system with a wireless extension through the use of Java servlets on a Web server to allow the data to be e-mailed as an attachment to a user-specified e-mail address (Palmer et al. 2002). This ensures that the NIS has a cross-platform future and can migrate from one device to another to take full advantage of the J2ME networking features.

A preliminary study of an **Emergency Pre-Hospital Care Communication System** was conducted for Northern Westchester Hospital (Park et al.). Many hospital emergency departments are exploring new communication and information technologies that will assist them in providing higher quality of care by improving the speed of flow, the consistency, and the accuracy of information shared among all the parties involved in an emergency response team. This study describes some currently available or on-the-horizon communication and information technologies that may be appropriate for use in the emergency services field, discusses three systems currently being used by other hospitals, and provides three alternative approaches to obtaining the type of emergency communication system that will best fit the needs of Northern Westchester Hospital's emergency department. The study found that the solution to be chosen should depend on the time frame allotted for the project, the funds budgeted, and the number and skills of the staff members responsible for implementing the system.

The **Medical Vital Sign Wearable** computer monitors a patient's vital signs, specifically heart rate and breath rate, which serve as indicators of a patient's immediate general health. If performed on a continuous basis and monitored remotely, it could assist medical support personnel. For example, each patient could be equipped with a medical status monitor that constantly reads blood pressure, pulse, respiration, and blood oxygen level, and a built-in expert system could determine when the patient's condition warrants attention and, if necessary, automatically transmit an alarm. This work extends that of a West Point student project in which a liquid-filled sensor pad placed close to the skin captured a signal that was processed by digital filtering to extract the heart and breath signals (Tappert et al. 2001). Recently, we became aware of a new, similar product, the LifeShirt, which is a lightweight shirt with embedded sensors that measure respiratory function, heart rate, posture, and activity level, with optional peripheral devices to measure blood pressure and blood oxygen saturation (VivoMetrics Website 2002).

VoiceXML and InkXML systems

Three projects involved VoiceXML and/or InkXML. The **VoiceXML Application Development Facility** was created to facilitate VoiceXML application development, and several small applications were used to test the system. The lab provides a gateway to develop voice applications, the interface for developing applications together with a template library, the capability to enable novices to use the code library to learn about and to build advanced applications, and facilitates both novice and expert developers in deploying multiplatform applications. The laboratory hardware consists of a Cisco router for Voice Over IP, the IBM Voice Server (provided by IBM), a Local Area Network (LAN), the Public Switched Telephone Network (PSTN), and a Firewall for the Voice Server. A minimal prototype of the facility is now operational, and upon completion of the facility, the architecture of the VoiceXML studio should permit the registration, development, and deployment of an application. The studio essentially enables the user to load his/her application URL that can be referenced by the IBM Voice Server.

Another team worked on **VoiceXML Applications**. The primary one, a voice-enabled Web-based absentee system (Gallivan et al. 2002), was implemented on the TellMe voice portal (TellMe Voice Portal 2002). It was tested by the class of software engineering students; students who intended to miss a class called the VoiceXML telephone number and were led through an automated dialog to record in a database his/her name, the date and time of the call, the courseID, and the date he/she would miss class. The system provides the instructor and other administrators with a permanent record of absentees that can be accessed and displayed in various forms through a Web interface. A more useful application of such a system would be for the university, or for any reasonably sized organization, to record absences or work time missed by its employees. Rather than calling a secretary, employees would telephone the system to report their absences, and the employer could then access this information through the Web interface; other departments (or systems) needing the information, such as payroll, could also access the database. This team also analyzed a telephone survey application requested by a psychology professor at SUNY New Paltz. This application differs from the usual VoiceXML applications because it requires the server to initiate the telephone calls rather than receive them. In this case, the server places the calls and, when the person answers, the application dialogue conducts the survey and stores the responses in a database. Although this application was not implemented because voice portals like TellMe only allow applications that receive calls, it should now be possible to develop such applications on our new VoiceXML facility.

A third XML system, the **Multimodal Voice/InkXML System**, combined voice and pen input using the standard voice and ink XML formats (Trabelsi et al. 2002a, 2002b). Just as a standard VoiceXML format that facilitates the development of voice applications has been accepted, so the acceptance of a standard InkXML format to facilitate pen applications is anticipated once it is developed. The student team developed a multimodal interface architecture that combines standardized voice and ink formats to facilitate the creation of robust and efficient multimodal systems, particularly for noisy mobile environments. By providing mutual disambiguation of input signals and superior error handling, this architecture should broaden the spectrum of users to the general population, including permanently and temporarily disabled users. Integration of VoiceXML and InkXML provides a standard data format to facilitate Web-based development and content delivery. Diverse applications ranging from complex data entry and text editing applications to Web transactions can be implemented on this system, and a prototype platform and sample dialogues were developed.

Cluster and grid computing system

One team proposed its own project, the **Cluster/Grid Computing System**, and developed a high performance computing facility by co-opting idle and/or underutilized computer workstations to create a virtual computing pool (Clarke et al. 2002). While the idea is not new, it is gaining greater acceptance in academic institutions that possess enough raw computing power to do distributive computing without the need to buy a high-end dedicated computer. During the first semester, the team constructed a cluster computer consisting of five PCs and demonstrated a substantial speed improvement of the cluster over a single PC performing the calculations of a standard ray-tracing problem in computer graphics. For the second semester, the team developed a grid computer for molecular calculations by choosing a computation-intensive molecular simulation package and running tests in the student computer-lab facility that is highly used by students during peak hours. Here, depending on the nature of the simulation with respect to the number of atomic interactions that need to be calculated in real time, it was demonstrated that the more compute nodes attached to the simulation the less intrusive the job was to the user of any workstation in the grid.

Benefits of Real-World Projects

In this section we describe the various benefits of having the computer science students develop real-world systems for real customers. Overall, these projects result in a beneficial outcome for all concerned.

Customers receive valuable systems

The customers benefit from the systems created for them by the students. In some cases, this amounts to a monetary savings, because the customers do not have to outsource the projects. The university itself can greatly benefit by having small projects completed by students. Not only is there a monetary benefit, but also students often do a better job because they are more motivated and may have a better understanding of the university's needs. In other cases, the customers receive systems they might not obtain under ordinary circumstances. Sometimes this is simply because funds for the project were not in the budget. For other situations, such as for the research-oriented systems, there is often no standard procedure for getting the system constructed.

Students develop technology, team, and professional skills

Developing real-world systems for real customers is a stellar real-world learning experience for the students, as individual technologists, as team members, and as maturing professionals in computing. Individually, the students learn technology skills, critical thinking skills, and how to be innovative and creative. They learn the technology skills necessary to develop real-world computer information systems. Through project reviews and team presentations, the students also learn about the various technologies used in other projects, and they especially appreciated the exposure to the projects involving cutting-edge technology and research.

Working in teams, the students learn fair-mindedness, intellectual humility, intellectual integrity, and the ability to work with others to produce useful systems and to take responsibility for them. Because most of the students are employed full time in various areas of computing, they bring their knowledge and expertise to bear in their project work, and by exchanging information, they learn from each other in this student-centered learning environment. The students also benefit from interacting closely with fellow students from diverse cultures and with diverse technological skills.

As maturing professionals, the students learn how to act in the computing field not only as technologists but also as value providers. By working with real customers in developing their project systems and focusing on human-centered computing, the students learn important value skills. This learning paradigm fosters lifelong habits for learning and the application of critical thinking and value skills.

Promotes interdisciplinary collaboration and Pace and local community involvement

These projects involved two communities, the university community and the local community external to the university. Within the university community, many of the projects involved interdisciplinary collaboration with other departments, such as the medical projects with the nursing school, the online survey project with the assessment department, and the involvement with the business school and DoIT. The work with the SUNY New Paltz psychology professor extended our collaboration to the greater university community. The projects also extended into the local community, with the projects involving Northern Westchester Hospital and IBM, to provide the students with off-campus experiences and to foster an extended community for learning and growth. With project customers coming from the local community as well as from the university community, the project work brought to light how knowledge of computing and information technology connects with personal and social responsibility. Interestingly, we found that having projects that dealt with both the Pace community and the local community led to a blurring of the boundary between those communities.

Furthers student and faculty research

Seven of the project systems are related to student and faculty computer science research that is ongoing and expected to continue. Three concern pattern recognition: the Experimental Handwriting System, the User Verification System, and the Rare Coin Grading System; and the first two of these are related to security and personal identification. Three concern XML: the VoiceXML Application Development Facility, the VoiceXML Applications, and the Multimodal Voice/InkXML System. Finally, one concerns wearable computing devices: the Medical Vital Sign Wearable computer. Seven other systems are research-related but are not related to ongoing student-faculty research. Two concern wireless technology: the NIS Wireless Extension and the Emergency Pre-Hospital Care Communication System. Two concern education-related research and were of short-term interest to the faculty customers: the Project Group Assignment System and the Test Item Reliability Analyzer. The two nurse information systems concern handheld computers and the J2ME, J2SE, and J2EE computer languages and, although not representing ongoing research by CSIS students and faculty, are of continued interest to the nursing school as a developing application that, due to its cutting-edge nature, should to be of interest to next year's students as a continuation project. Finally, one deals with supercomputing (short-term student interest): the Cluster/Grid Computing System. Clearly, these real-world projects profoundly foster and further student and faculty research.

Enhances relationships between the university and local technology companies

Some projects drew on the intellectual capital pool of local companies. For example, three projects benefited from collaboration with IBM scientists: the VoiceXML facility team received a copy of the IBM Voice Server from the IBM Speech group, the vital-sign wearable computer team received advice and use of an electronics lab from an IBM scientist, and the Voice/InkXML team interacted with the IBM Pen Technologies group. Furthermore, the IBM Pen Technologies group is interested in an extended collaborative relationship to pursue research in areas of mutual interest and to have students test their handwriting research systems.

Increases national recognition of the university

Many of the benefits indicated above strengthen the university's external image and identity. Students can also present papers on their project work at technical conferences, and those working on cutting-edge technologies can enter competitions. This is already happening – for example, students and faculty have presented papers related to these systems at conferences (see references), and several students won prizes in IBM's VoiceXML contest.

Cost of Real-World Projects

Although far outweighed by the benefits, the cost of using real-world projects is significant. There is an increased load on the instructors to solicit and interact with customers, to set up the projects, to work with the computer support personnel to set up the project development infrastructure, and to monitor the systems development process. There is also significant computing infrastructure required to facilitate the development work.

Setting up projects, forming teams, and assigning projects

The first task is to come up with the projects, and this process is conducted primarily during the summer prior to the beginning of the school year. For this year, eight projects came from those interested in developing systems to further their research (CSIS faculty, sometimes in collaboration with local technology companies, and, in one case, with a DPS student), one came from the instructor's course need (Project Group Assignment System), one came from the students' interest (Cluster/Grid Computing System), and the remaining eight came from contacts with and e-mail solicitations to faculty of CSIS and other departments.

The instructor then works with each of the customers to size and shape the project to be an appropriate systems development experience for the students, and this results in a written project description that is posted on the "projects" page of the course Website. For customers not familiar with computing systems, the instructor often performs most of this task independently. The inducement for the customers' involvement with the students throughout the year is the anticipation of receiving a useful system, although they are warned that the primarily purpose of the projects is to provide the students with a good educational experience and that not all projects are successfully completed.

The next task is to form the student teams and assign each team to a project. This year the students formed their own teams, the teams listed their project preferences, and the instructor assigned teams to projects based almost entirely on their preferences. There are significant problems with this approach, such as the tendency of students to choose group members based solely on friendship and that the assignment of projects can be perceived as unfair by students who did not obtain their first choice. For this reason, one of the projects this year was to develop a group assignment system to automatically assign students to project teams based on compatible project interests, compatible time schedules and geography (work and home location) for group meetings, and the diversity and appropriateness of students' computing and leadership experience; this system will be used next year to automatically group students into teams and to assign projects to the teams.

Systems development process

The development of the computer information systems requires a systematic approach by the students and proceeds through an evolutionary process model consisting of analysis, design, build, and test phases. The first phase requires the students to work closely with their customer to understand what is desired, usually by developing use cases and use scenarios about how the system will be used; to plan the project; and to perform a risk analysis, all culminating in a written requirements document. The second phase involves designing the system using various analysis and design tools, and this work varies greatly depending on the type of system. For example, a database backend requires database design methodologies, whereas a Web interface requires interface and Web design engineering. The third phase is the actual construction of the system and, depending on the project, usually requires the use of one or more computer software languages and/or database implementation. The fourth phase is the testing of the system to ensure that it meets the customer's requirements and that all of its functions operate correctly.

In the software engineering sequence, the students were required to complete a working system prototype with the core components of the required functionality by the end of the first semester. Because the first semester of the course focuses on the traditional systems development methodologies and the second semester on the object-oriented ones, the students reengineered their systems using object-oriented techniques during the second semester to culminate in a robust and complete system. For the pervasive computing course, the systems were completed in one semester, which was possible because of the course's greater emphasis on project work and because most of the students were also in the software engineering course and therefore were familiar with systems development.

Project development infrastructure

Since most of the projects used the client/server architecture, a Pentium II NT development server was set up for the students to develop their systems. The software installed included Cold Fusion, PHP Hypertext Processor, Active Server Pages (ASP), MySQL, Tomcat, and Microsoft Office. This server was independent and separate from the other CSIS servers so that students could not corrupt data or interfere with operations on CSIS production servers. A variety of database-related software was used by the ten client/server systems and the VoiceXML absentee system that also used a backend database and a Web interface, the latter as an alternative to the telephone input and for displaying the results (Table 1). The student teams used three scripting languages (Cold Fusion, PHP, and ASP) to communicate with the databases and two database systems (Microsoft Access and MySQL). Several projects also used Java-related software, such as Java servlets, and Tomcat was installed to handle the processing of that code. An additional server was made available for the VoiceXML facility project and six old Pentium I and II PCs, network cards, and network cables were made available for the cluster computer project.

The project development infrastructure will be enhanced next year to reach a higher level of professionalism in project development. The NT development server will be upgraded and a Unix server added – a Solaris-Oracle configuration. A production server will also be added toward the middle of the spring semester to house the final systems and to give the students practice in moving their system from one environment to another.

Conclusions

In 2001-2, Pace University CSIS students developed real-world computer information systems for actual customers. Developing real-world systems provides an excellent setting for teaching students the technological skills of the discipline, team-related skills, and value skills by following a human-centered development process. It also provides a vehicle for fostering interdisciplinary collaboration, encouraging student involvement in the university and local communities, furthering student and faculty research, enhancing relationships between the university and local technology companies, and increasing national recognition of the university.

Abstract: This exploratory study evaluates descriptive data from two sources; the evaluation of a web-based learning environment and the application of the Living Systems instructional design model to the development of a second, online, distance-education course. This inquiry clarifies the relationship between the nature of the knowledge type, choice of instructional methods employed, and capabilities of the available web-based technologies. This effort seeks to determine the practicality of a design template that matches the structure of specific knowledge types (procedural, declarative, complex-dynamic) with pedagogical methods, and then pairs those methods with the current features of web-based technologies. The results of this initial study will inform the development of a large-scale evaluation of web-based learning environments across varying content areas.

Introduction

This paper discusses the relationship between three salient aspects of web-based learning environments (WBLE): the information architecture of the course material, the interaction design of the content, and the information/page design of the instructional system or site. The Living Systems ID model (Plass & Salisbury, 2001) addresses these three aspects of a WBLE in detail. The information architecture or organization of a WBLE may be derived from a careful assessment of the nature of the knowledge type (procedural, declarative, complex-dynamic) or a combination of these broad categories. The interaction design of the WBLE consists of navigation options and more importantly the pedagogical methods employed in the teaching and learning process. The application of certain pedagogical methods within a WBLE is often mitigated by the affordances of available technologies. This study appropriates the Living System framework and emphasizes the relationship between knowledge type, pedagogical methods, and web-based technologies to create a template by which WBLEs can be developed and evaluated. It proposes to extend Mioduser's (Mioduser, Nachmias, Lahav, & Oren, 2000) analysis of the current state of pedagogical methods and technologies predominantly used in WBLEs by clarifying the relationship between knowledge type, information architecture, pedagogical methods, and available technologies.

The inherent organization derived from various knowledge types leads to specific types of navigation, often mitigating design choices. The interaction designs and navigation options that flow from procedural knowledge, to extend the previous example, tend to be linear. This is contrasted with a more dynamic or complex type of knowledge that would tend to be non-linear with multiple pathways to associated information. The instructional methods are also constrained to some extent by the nature of the knowledge and the organization of the content that is derived from it. Procedural knowledge may lend itself to more behavioral approaches, where component skills are requisite before more complex tasks can be performed.

The information/page design and the technological features incorporated into this example may be different from those used in another application with a different type of knowledge. In a web-based environment, there are a limited amount of tools to choose from. The use of those tools should flow from the pedagogical methods determined in the previous 'step'. However, the technology constrains us to a certain set of methods and an inappropriate use of the tools at time.

Study

There are many different categorizations of knowledge types used for varying reasons. The broad categories typically agreed upon include procedural, declarative, and some version of a dynamic or complex knowledge (often referred to structural knowledge (Jonassen, Beissner, & Yacci, 1993)). An underlying question this study addresses is whether or not content within procedural, declarative, and complex-dynamic knowledge types have an inherent natural order, even if that order is relatively complex and difficult to determine. If it is possible to identify a general order or structure within any of the knowledge types, then it may be possible to create a design template for WBLEs that includes both guides to appropriate navigation and pedagogical methods.

Method

Two WBLEs are the focus of the inquiry. One is currently in development and is to be delivered on-line during the Fall semester of 2002. The second WBLE is currently in use as an instructional website. Interviews with content developers, instructors, and students, and document analyses constitute the data gathering techniques. Evaluation of data occurs in three distinct areas identified within the Living Systems ID model. Data will be assessed based on knowledge type, choice of pedagogical method(s) chosen to communicate content, and how those instructional choices were either constrained or enhanced by available web-based technologies.

Various organizations of differing types of knowledge will be compared with hierarchical, linear/sequential, associative/web-like, and grid structures (Lynch & Horton, 1999) to determine if patterns emerge. A range of commonly accepted constructivist and behavioral methodologies will be matched with the content of the instruction during development of the online course. This range of methods will be used to assess a web-enhanced course currently in use as an additional source of data. A list of available web-based technologies will then be paired with the constructivist and behavioral pedagogical methods to determine suitability of each method on the web.

Results and Discussion

The results will inform the design and direction of a larger survey of WBLEs to be conducted in the Fall of 2002. If patterns and generalities emerge, the practicality of a template for the design and evaluation of WBLE will be furthered explored. The need for considered and parsimonious decision making in the development of WBLEs continues to increase as educational environments continue to migrate in that direction and instructors are faced with a bewildering array of issues and choices.

The effectiveness of educational technology: Will the "Enhancing Education Through Technology Act of 2001" really expand our knowledge of teaching and learning with technology?

Introduction

The recent reauthorization of the Elementary and Secondary Education Act of 1965 (EASA), also known as the No Child Left Behind Act of 2001 (NCLB) provided broad changes encompassing many areas of public education in the United States. Accountability, expansion of school choice, increased focus on reading skills, and greater flexibility for state and local authorities are central pieces of the Act. Another area where emphasis and funding have increased significantly with the current reauthorization is educational technology.

In 1994, the reauthorization of EASA known as "Improving America's Schools Act of 1994," (IASA) allocated $200,000,000 for Title III educational technology programs (Improving America's Schools Act of 1994, § 3114 (1995)). While this is a significant amount, Title III funding for fiscal year 1995 pales in comparison to funding for FY 2002. The most recent reauthorization has appropriated $1,000,000,000 for technology in education under the Enhancing Education Through Technology Act of 2001. Of this funding, $980,000,000 is earmarked for state and local initiatives while $20,000,000 has been set aside to fund federal programs. Furthermore, $15,000,000 of the federal allocation has been committed to a long-term evaluation of technology and its effect on teaching and learning (No Child Left Behind Act of 2001, Part D § 2401 (2002)). This longitudinal evaluation on the effectiveness of technology in learning promises to, "address a gap in knowledge that for years has frustrated both educators and policymakers" (Trotter, p.1, 2002). The Department of Education's Office of Educational Technology has yet to announce specific plans for the study so as of this writing, the author is not certain as to whether this project will consist of one comprehensive evaluation or a series of projects.

Technology has come to play a central role in teaching and learning over the past 15 years. During this period, educators and other researchers have evaluated many aspects of teaching and learning with technology. This paper will address two questions:

1. What criticisms and obstacles may have impeded past research?
2. What are the implications of these obstacles for the study proposed under the NCLB Act of 2001?

Each of these questions are important in light of the fact that considerable time and money have been set aside in an endeavor to answer the question decisively. Countless hours and dollars have already been devoted to this subject and one finds little difficulty in locating an "expert" on the topic. However, since the research has yet to provide satisfying results, it seems reasonable to consider why this is the case and what past research suggests about future research in learning and technology?

Literature Review

The astronomical growth of personal computing has brought space-age technology to the classroom. The computer has found its way into every corner of education. From college to kindergarten, educational technology has become the rule rather than the exception in a relatively short span of time. Research into the effectiveness of this technology has been conducted on all fronts from both federal and state government, universities and colleges, and even local educational agencies. Given the emphasis that educational technology research has received over the past decade, a large body of information exists. However, educational technology research conducted since 1990 has been wide-ranging and has attempted to cover a diverse spectrum. At times, the findings have been contradictory and subject to dispute. Kirstie Bellman succinctly argues that, "… the difficulty with educational technology is how to get past the hyperbole and develop the right technology with the right classroom and pedagological practices that will ensure that it is supportive and not destructive for learners and for educators" (2001, Lines 2-5). Before spending more research dollars, we should consider what we have learned from past experience and what, if anything, it tells us about the future. The next section of this paper outlines two problems with past research: breadth of focus and methodology.

Research Criticisms

Research in educational technology encompasses a broad range of categories, sub-categories, and topics which all compete for scarce attention and even scarcer funding. It is this broad range of interests that make rigorous research in this area even more problematic. Because educational technology is at once, a learning issue, a teaching issue, an administrative issue, a social issue, and a political issue, a useful and effective body of research will necessitate the study of all the critical areas of educational technology and this challenge is nothing short of enormous.

One aspect of educational technology research that has received strong criticism has been methodology. Critics have complained about, among other things: a lack of scientific rigor, an over reliance on anecdotal evidence, and technological bias. Waetjen (in Wicklein, 1992) asserts that, "Die-hards claim that research isn't needed and instead offer up dozens of anecdotal accounts of students who have benefited from taking courses in technology education…Only research results will be convincing." (p. 4) While Waetjen was referring specifically to technology education; a minor part of the educational technology landscape, Reyna was addressing the broader issue of educational technology when she criticized a reliance on tradition, superstition, and a reliance on unfounded beliefs (Reyna, 2002).

Feuer and Towne (2002) describe three more problems with previous educational technology research. Researcher bias is a problem because scholars who are closely involved in the environment and frequently even the educational lives of the other participants have conducted a great deal of research (2002). Proximity between researcher and participant has been generally unavoidable and not always undesirable, but it is an area that must be addressed. Patton (1990) suggests that, "getting close to a program through firsthand experience permits the evaluator to access personal knowledge and direct experience as resources to aid in understanding and interpreting the program being evaluated" (pg. 205). However, if the researcher fails to consider her own experiences and background, her participation may influence the findings. This participation or influence would have serious consequences for the validity of a quantitative study and the trustworthiness of a qualitative study.

The second problem described by Feuer and Towne is one of description versus prediction. Educational technology research, and indeed educational research in general has produced research products which are descriptive in nature. The results do not predict future events, behaviors, or changes but merely describe what has occurred in a given situation in the past (2002). Just because a research project is carefully designed, conducted, and reported doesn't make it relevant or useful to a practitioner outside of the research environment. Good educational technology research must have some utilitarian value to practitioners in "the field," particularly if it is supposed to describe and predict how technology facilitates learning in the classroom.

The third criticism involves the diverse and decentralized structure of public schools in the United States. Local control creates a situation where a number of independent local programs may be referred to by the same title or other descriptor but have no relationship whatsoever with other programs of the same name (Feuer & Towne, 2002). This creates a situation where information is either, not generalizable to other populations, or it is accepted as relevant because of similar titles and terminology when, in fact, it is completely unrelated to the current program or programs of interest. The democratic and geographic nature of our federal, state, and local institutions makes it extremely difficult to generalize many findings in educational research. What works for a small rural single school district in Arkansas is not likely to have much relevance for an urban district that may have 100 different schools and vice versa. I think that this is probably the most significant difficulty in conducting research related to educational practices in this country. Our continued preference for local control makes comparison between schools extremely problematic.

Methods

To illustrate the vast body of educational technology research conducted in the past few years, the author of this paper conducted a survey of common educational technology research areas. Using target areas described in the "Enhancing Education Through Technology Act of 2001," the researcher conducted a search of the Educational Resources Information Center (ERIC) database (http://www.askeric.org/) (No Child Left Behind Act, 2001). While the ERIC database does not provide a complete list of all research conducted in the past 12 years, it does offer a reasonably extensive cross-section of data. The current search was conducted by combining the terms 'educational' and 'technology' with each of the following terms or phrases: teacher training, technology integration, assessment and evaluation, and finally, standards and frameworks. The keyword search method utilized the Boolean operator 'AND' and was restricted to the years 1990 through 2002.

Results

The search results in the table below illustrate the breadth of research in the field of educational technology during the 1990s. The search terms, assessment and evaluation, yielded the smallest number of documents for the 12-year time period. However, the 2,329 documents produced by this search still represented an average of 3.73 new articles, reports, and presentations every week from 1990 through the end of 2001.

Search Terms	Results
Educational AND technology ONLY	30,342 documents
Educational AND technology AND teacher training	2,539 documents
Educational AND technology AND integration	5,308 documents
Educational AND technology AND assessment AND evaluation	2,329 documents
Educational AND technology AND standards	2,699 documents
Search conducted: March 11, 2002. http://www.askeric.org	

The original or primary search terms, 'educational' and 'technology' provided the greatest number of results in the ERIC database search. It is assumed that this search yielded all the documents represented by the secondary search terms as well as other educational technology terminology not searched for this report. The ERIC search yielded a total of 30,342 individual documents for the same period from 1990 through 2001. It would take a very diligent researcher to keep up with the approximately 48.65 new educational technology documents that were created every week. The volume alone is enough to perplex and discourage even the most committed educational technology researcher. Given the vast array of research areas which fall under the collective heading of educational technology, it is not difficult to see why research may appear to be insufficient and lacking in meaning and relevance. Unfortunately this is a problem for which there appears to be no clear or easy solution. By nature and definition, the field of educational technology does and will continue to encompass diverse areas of interest as demonstrated by the ERIC search. The task will continue to seem overwhelming and the best opportunity to improve research quality is through more focused, scientifically based research.

Discussion

Given the vast body of research that has occurred since 1990, what direction should future researchers take when examining the effectiveness of educational technology? Melmed (1995) provides a typical example of a broad-based initiative to study the effectiveness of educational technology. In 1995, the U.S. Department of Education requested assistance from the Rand Corporation in responding to the GOALS 2000:Educate America Act of 1994. Melmed served as chair of a 2-day workshop: Workshop on Technology-Supported Student Learning: Outcomes, Effectiveness and Cost. The workshop goals were wide-ranging and diverse. Many of the research questions were similar to the same ones framed in the current research climate.

Unfortunately this example is also an indicator of why little has changed. A two-day seminar that featured 14 presentations was supposed to answer questions and improve education in this country. Again, the 14 presentations were, in general, descriptions of programs and projects deemed successful by their presenters. While many of these may have been valuable in the original research context, there is little reason to suspect that much impact was felt by those not involved in the initial project.

Feuer & Towne (2002) have suggested six principles to guide future research in education that are worthy of mention.

1. Pose Significant Questions That Can Be Investigated Empirically
2. Link Research to Theory
3. Use Methods That Permit Direct Investigation of Question
4. Provide Coherent Chain of Rigorous Reasoning
5. Replicate and Generalize
6. Transparency and Scholarly Debate

These ideas are nothing new to researchers in other discipline areas and are not even novel to educational researchers. However, in educational research most of these principles have not been used systematically or coherently. Given the lofty goals of the NCLB Act of 2001, strict adherence to these basic principles of research will be crucial to determining what educational technology practices and programs are effective and what programs should be abandoned to the scrap heap of experience.

Valid and relevant research requires a thoughtful and systematic approach. The pervasive nature of technology in teaching and learning necessitates research for understanding in a broad area including: teacher training, technology integration, technical literacy for students, and access. Despite the fact that some of these areas are not technically interrelated, none can be ignored. The critical need will be to prioritize focus areas to maximize opportunity for real and useful research-based results.

In order to realized the lofty goals set forth in the "No Child Left Behind" Act of 2001, educators, administrators, and politicians will need to reach some consensus regarding priorities for study. However, this will be a tremendous challenge because, regardless of the technological advancements available to students and educators, the fundamental question remains one at the heart of all educational reform: What is the purpose of public education in this country and what are appropriate goals for realizing that purpose? Any research and reform efforts that fail to honestly address this question are likely to face the same problems and shortcomings of previous research.

Accessible Adult Learning in the Health Professions:
Interactive Uses of Distance Technology

Abstract: This paper describes a study of students' perceptions of the impact of accessibility and interactivity on successful distance education in the Health Professions. The study utilized both quantitative and qualitative data to determine how students perceived issues of accessibility and interactivity affecting their success in distance courses. Our research found that both accessibility and interactivity are crucial to students' success in and satisfaction with distance education courses. In fact, issues of accessibility and interactivity are interconnected to such an extent that they can work together to either support or detract from students' success. Students, instructors, staff, departments and the university administration must work together as a team to create the most readily accessible and interactive distance education possible.

I. Introduction

In our post-industrial information society, knowledge accumulates quickly and needs to be disseminated quickly, and at frequent intervals, to those who need it. As a result, education can never end. Life-long learning must be encouraged and facilitated to allow for on-going professional development and connections with global learning forums. This process benefits both the learners and the communities they serve. This is particularly true in the health professions.

Research has shown that potential students in the health professions often fall through the gaps in traditional learning environments. For example, rural learners, adult learners, and disabled learners often find it impossible to leave their homes to seek further education. They are often located too far from a learning institution, or are unable to take the time to leave jobs or dependents to seek further education. Those people who do not have the opportunity to access education at a distance to up-date their knowledge and skill sets and further their career goals, are at a disadvantage.

Distance education, increasingly offered via the Internet, provides a solution to this need. The ability to access the technology utilized in distance education is a key component in delivering a successful on-line educational programme but barriers to access remain. As recently as 1996 Angus Reid reported that only 39% of women, compared to 61 percent of men, had Internet access. (Joseph, 54, originally cited in Menzies, 1998) Many rural dwellers still do not have access to high-speed Internet, while disabled students are isolated by web interfaces that do not recognize their particular needs.

The challenge for educators is to retain quality in education whilst extending accessibility to students who would otherwise remain at arms length from their programmes. There has been a tendency to assume that education in the health professions must necessarily be on-site to deal with the challenge of linking theoretical knowledge with the practical development of competence. Efforts have been undertaken bydistance education instructors to promote the interactivity encouraged in the live classroom in the virtual classroom. Experts agree that the best way to accomplish this goal is to make the virtual classroom experience highly collaborative and to promote discussions between students as well as between students and the instructor. This has been one of the key challenges in providing successful education in the health professions.

A review of the most current literature on issues of accessibility and interactivity in health professions distance education confirms the importance of these two key themes in creating a successful programme. While the literature is generally positive about distance education, the purpose of research in this area is to present solutions to recurrent difficulties encountered by many programmes. Some researchers are looking towards educating instructors in new pedagogical techniques suitable for distance education, others are involved in developing and testing computer-based systems that will assist student learning at a distance. Some researchers are also beginning to turn to their students for perspectives, advice and insight about their perceived success and satisfaction with distance learning (Cartwright, DeBourgh, Draude & Brace, Lesh et al., Mamary, Nelson, Thiele).

The ideal health professions course provides plenty of opportunity for students to communicate, cooperate and collaborative with one another. Interactivity between students, and between the instructor and students , promotes community and connection within the course creating support-systems which facilitate learning. (Geer, Liaw & Huang) Group work mimics the real-world experience of health professionals who must often work in teams to understand and cope with the workings of many complex systems including the human mind and body, the administration and management of staff and patients, and the moral and ethical dilemmas they inevitably encounter. (Niederhauser, Spector & Davidson, Orrill, Lankard Brown). Thiele notes that "the current and future health care environment demands a collaborative approach to work. Modeling this expectation in the nursing curriculum provides essential preparation for the multi-disciplinary partnerships that are a requisite for providing quality care, now and in the future" (Thiele, 202).

Despite the advantages the technology has to offer, accessing a virtual course rather than attending a live class is often fraught with difficulties mostly caused by the technology, specifically low-level computer literacy. Some students are afraid of the technology and/or lack the technological skills they need to access and complete the course. This problem can be exacerbated

BEST COPY AVAILABLE

by the lack of the instructors' technological skills or the lack of technological support for both instructors and students from the institution. In some cases, the inability of the institution to supply the necessary technology, to upgrade old systems, or to provide technicians who are capable of setting up complex systems due to financial constraints, affects the access students and instructors have to distance education possibilities. (OLT, Muirhead, Terpstra in *Distance Learning*). Administrators, technical-support providers, and library personnel all need to be trained to assist distance education students. Faculty need to be supplied with access to technological and pedagogical professional development. (OLT, Muirhead, Sykes Berry & Mullaly-Quijas in *Distance Learning*, Franklin in *Distance Learning*) They also need to offer their courses using a variety of learning technologies to facilitate accessibility. (Lankard Brown, Cragg & Doucette in *Distance Learning*) Furthermore, students need to assist themselves by taking computer and orientation sessions before beginning a course to assure they have the requisite skills necessary. Students also need to be willing to problem-solve with the technology in the same way as they problem-solve issues that they face in their daily professional lives (Clarke).

According to the literature, achieving student success and satisfaction with accessibility and interactivity are key components in attaining overall success and satisfaction with distance learning. Studies show that good pedagogy that promotes collaborative learning and communicates expectations clearly to students can enable students to enjoy and succeed in a course despite the technological difficulties they may encounter. (DeBourgh) Ideally, though, the smooth working of technological systems and support services facilitates the ability of students to interact with the course, the instructor, and other students and thus to obtain the maximum benefits of the health professions programmes offered by distance.

II. Specifics of the Dalhousie Health Professions Study:

Five departments within the Health Professions Faculty at Dalhousie University, Nova Scotia, Canada (all offering a varying number of distance education courses and programmes at the undergraduate and graduate level) collaborated to determine their students' perceived satisfaction with the accessibility and interactivity of their distance education.

This Project was conducted in concert with the following internal partners at Dalhousie Univesity: Office of Instructional Development and Technology, Atlantic Health Promotion Research Centre, and the Academic Computing Services. The following external partners were involved: Office of Learning Technologies of Human Resources Development Canada, and the Workers' Compensation Board of Nova Scotia.

ii. Key Themes

Accessibility:
The different ways in which the technology of
distance education is available to learners.

More specifically, ***accessibility*** refers to the students' ability to gain easy access to the course, to be able to access support systems to aid with technological difficulties, and to have access to a variety of ways to interact with the university administration, the course, and the learning process.

Interactivity:
The inter-play and exchange in which individuals and
groups (learner-learner, instructor-learner) influence each other.

More specifically, ***interactivity*** referred to the receptivity of students and faculty to the use of different technologies (chat-rooms, discussion boards, teleconferencing, email) and methods (social rapport building activities, course design, the nature of the communication in a course) to communicate with one another. The term interactivity also referred to students' and faculty's perception of these technologies in enhancing or detracting from their opportunity for discussions and collaborations and the usefulness of these interactions in their learning process.

iii. Student Demographics

In the Faculty of Health Professions at Dalhousie University, the demographics of the adult distance learning were in accordance with those generally described in the literature. Based on survey data, the majority of students were:

- female
- between the ages of 25 and 55
- employed full-time while maintaining part-time student status
- accessing academic courses most often during the evening
- responsible for caring for dependents at home

A significant number of students were rural dwellers.

3. Methodology

i. The Objectives of the Project were:

I. To analyze technology and learning needs identified by adults at the beginning of distance education courses in four Schools and the Disability Management Programme in Dalhousie's Faculty of Health Professions during the 1999/2000 and 2001-2002 academic year;

II. To trace and analyze the progress of learning though distance education throughout course delivery over two years in the four Schools and Disability Management Programme; and

III. To analyze summative evaluation data, and synthesize and disseminate findings on interactive uses of distance technology in a range of entry level, graduate, and continuing education in four different health professions.

These objectives formed the basis for the development of a multi-methods study gathering both quantitative data via surveys and qualitative data via focus groups. A Survey was developed, piloted and redesigned to capture student perspectives on accessibility and interactivity in their distance learning experience in five departments of the Faculty of Health Professions. The Surveys were conducted via email, however students were assured of confidentiality. Survey #2 had a higher response rate likely due to the fact that a pre-survey message was sent reminding students about the survey. Focus Groups were held throughout the two year project. All Focus Groups were conducted by teleconference interviews by an external research group. The final survey questionnaire is described in Appendix A. Table II identifies the data collection process and Table III details the dates the methods were employed and the numbers of participants involved.

4. Results

I. Surveys

1. Students' Technological Confidence

Technological Skill	% of Students 'very confident'
email	73%
keyboarding	72%
word-processing	70%
Internet applications	22%
use of on-line library sources	17%
Trouble-Shooting	14%

2. Availability of Modes of Distance Education

Mode of Distance Education	% of Students Perceiving Mode 'very available'
Internet/Web-Based	71%
Teleconferencing	28%
Videoconferencing	2%

3. Helpfulness of Various Methods in Preparation for Course

Method of Preparation for Distance Education	% of Students Perceiving Method of Preparation 'very useful'
Instructors	43%
Manuals/Literature	31%
Friends/Family	25%
Workshops	16%

4. Opportunity and Helpfulness of Student to Student Interaction

Nature of Student to Student Communication	% of Students Perceiving 'lots of opportunity' for Student to Student Communication	% of Students Perceiving Student to Student Communication 'very helpful'
Exchange of Personal Information with Other Students	65%	53%
Communication About Non-Course Content	34%	32%
Participation in Planned or Spontaneous Activities Allowing Student to Share Ideas	48%	54%

5. Promotion of Interactivity via Designed Activities

Participants in Communication	% of Students Perceiving 'lots Opportunity' for Communication in Designed Activity	% of Students Perceiving Communication in Designed Activity 'very helpful'
Communication Between Student & Instructor	77%	73%
Communication Between Student, Instructor and Other Students	77%	75%
Small Group Work with Other Students	49%	43%

II. Statistical Inferences from Survey Data

Factor Analysis tests performed on Survey #2 resulted in some generalizations and collapsing of data. Collapsing these questions allowed us to see to what extent the demographics are determinant of variations in response to the questions on accessibility and interactivity. After the results of Survey #2 were gathered, questions relating to accessibility were not collapsible. Questions relating to interactivity were generalized.

With regard to 'technological confidence' and 'interactivity there was no statistical difference in probability values in responses between demographics, thus generalized conclusions could be reached. No significant difference was demonstrated in interactivity between number of courses, age group, urban vs. rural dweller, and between those having dependents vs. those without dependents. However, a statistical difference was shown between full-time employed survey participants and those other-wise employed or unemployed. Full-time employed participants exhibited less confidence with the technology than the other group.

No statistical inference could be made with regard to sex due to the high number of female participants and the comparatively low number of male participants.

III. The Focus Groups

Students in the Focus Groups (Focus Groups #1,2,3) believed that having computer skills was the most important skill/experience in contributing to their confidence in distance learning. Most students hadacquired their skills by trial and error either at work or at school, although a few mentioned technical support and course work. They believed that technical challenges inhibited their access to distance education, followed by scheduling difficulties when teleconferences, for example, conflicted with work or family responsibilities. They also mentioned, secondarily, that the being able to work independently and to participate in a well-organized course helped their confidence with distance education.

The students found instructors most helpful in studying by distance, providing flexible hours and deadlines, although they resented instructors who they did not feel were fully committed to distance education or who were inexperienced with distance learning. They also mentioned the support of departmental staff and technical support as being helpful to them. They were frustrated by the administrative and library barriers to studying by distance, such as dealing with the Registrars Office, double-billing, the unavailability of on-line registration, no on-line access to marks and access to materials. They asked for improvements in these areas as well as for more technological assistance. They also stressed the need for well-organized professors who would give more feedback.

Students reported that all distance modalities had their strengths and weaknesses. They found discussion board communication most successful, although turn-around time could be lengthy in this mode. Teleconferencing and chat-rooms were praised for the immediacy of communication but complaints were made about scheduling such interactions and the inability of some students to keep up with the flow of the discussion. Instructors varied greatly in their ability to encourage interactivity and the nature of such interactivity, but most students felt that interactivity was encouraged by instructors through such methods as grading participation, questioning students or requiring students to post questions, or by discussing case studies or relevant web sites.

Most students felt the need for and managed to obtain some amount of informal interaction either on-line or via the phone or in-person where possible. The need to substitute some form of interaction for in-class interaction was high, but there was still often feelings of disconnectedness and loneliness amongst students. Still, students reflected that they were pleased that they had access to courses via distance.

Faculty and Staff Focus Group (Focus Groups #4,5) results supported the findings of the Student Focus Groups. They also raised issues that are specific to their perspective but which nevertheless affect the accessibility or interactivity of distance education. For example, although the departmental staff are willing and able to assist students with difficulties, this role takes up a lot of their time. For the most part, staff had been able to learn the technologies either through trial and error or via workshops to assist students but were as frustrated as the students, if not more so, by the lack of systematic administrative procedures to deal with distance education students. Faculty equally noted the ad hoc manner in which they have managed to learn the distance education technology and have adapted their classroom pedagogy for distance learning. Faculty noted the lack of university support in both contexts. Furthermore, they noted the excessive amount of time a web-based course takes to formulate and run and the lack of support or recognition such teaching work receives.

5. Recommendations for Change:

WHAT STUDENTS CAN DO:

- Students need to provide themselves with baseline technologies wherever possible and take workshops to up-date their technological knowledge
- Students need to consciously understand their learning styles to understand how they work best and where problems may arise for them
- Students should attend live orientations where possible, but definitely on-line orientations to the course and to the technology
- Students should be willing to commit themselves /be open to the collaborative learning process that the best on-line learning necessitates
- Students have to be prepared to work independently, manage their time, motivate themselves to get the work done
- Students should adapt technologies to suit their learning needs - ie. Taping teleconferences, printing discussions, forming partnerships with other students

WHAT INSTRUCTORS CAN DO:

- Provide orientation sessions for students - either live or on-line - technical/introductory to class - to other students and instructor
- Provide clear and detailed syllabus with course requirements and assignment instructions at the outset of the course
- assign groups on basis of time-zone, schedule, availability
- Faculty need to provide multiple weekly on-line meetings to facilitate full-time workers schedules and time-zone differences
- Commit themselves to the extra time an on-line course will take
- provide participation marks/mandatory participation to encourage student interaction on line and build community which will assist in the learning process
- make chat-room groups small so that discussion is more manageable - less threads to follow
- check up on students who have been absent/silent for too long

University Administrative Support For Faculty

- Provide professional development - in technology & pedagogy - for faculty developing on-line courses. Provide an on-line course for faculty in transforming courses into on-line courses. (This way faculty experience the on-line course from a student point-of-view, and they can learn the technology as they learn how to transform their course.)

- Provide more tech support to faculty developing on-line courses and increase faculty awareness of support systems already established on campus

- Provide a University Co-ordinator for distance learning where one person is in charge of distance learning policies and procedures and can oversee professional development of faculty in new technologies and new pedagogical approaches.

- Provide recognition for the amount of extra time an on-line course takes to prepare and conduct by faculty members, increase recognition for teaching achievement within the university

7. Future Partnerships and Catalysts for Future Research in Health Professions Distance Education

Engaging in this project has allowed members to realize that distance education has become a very legitimate method of offering academic course work in the health professions. Being part of the OLT group, including presentations to parties interested in implementing some kind of distance training, has shown that distance technology is a relevant approach to reaching persons who may not have been able to access particular courses in the past. Moreover, it is clear that the changes proposed by this project are very sustainable.

Beyond the study of accessibility and interactivity for student success and satisfaction with distance education within specific departments, other areas for further research in distance education in the health professions include:

1. A study of the gender/rural issue.

2. A study of how students research on-line in the health professions.

3. A study of how health professions students learn in a distance education environment.

4. A study of how health professions faculty adapt their pedagogy from the in-class to on- line environment.

The Project has found that issues of accessibility and interactivity are crucial to students' success in and satisfaction with distance education courses.

Coaching the transition to e-learning: re-thinking instructional design

Chris Trevitt
Centre for Educational Development and Academic Methods
The Australian National University

> 'There is not a simple "experiment" that involves pitting distance and on-campus education against one another to determine which is "better". The question basically is what is the best way to deliver different facets of an educational program. In many instances the answer will likely involve a mixed combination of synchronous and asynchronous experiences for both on- and off-campus programs.'
>
> 'The innovation opportunities of distributed learning involve both delivery and learning methodology. At present, technology appears to be driving many adaptations, and not many research faculty are involved in educational research and development. Educational objectives would be advanced if this trend were reversed and problems were formulated before a technological solution was sought and more funding were available to support the needed educational research.'
>
> (US Council of Graduate Schools, Policy Statement on 'Distance Graduate Education: opportunities and challenges for the 21st century': 1998, p18.)

Introduction

This paper reviews the experiences of a collaborative approach to the intense educational development involved in the transition to a successful technology -facilitated off-campus study program. Drawing on a history of many years of collaboration between the ANU educational development centre (CEDAM) and the Legal Workshop (LW) group in the Faculty of Law, the project spanned a 12-month academic year development period in 2001. The study program is a Graduate Diploma in Legal Practice (GDLP), taken by more than 150 students per year from all over Australia as well as overseas, many of whom are employed in a wide range of work environments. There are some 15 separate courses of study.

The institutional context is highly research intensive and gives emphasis to an on-campus education. Recently, however, the University has begun actively exploring distributed and flexible approaches in niche settings (such as that represented by the GDLP) which permit it to better meet changing national and student needs. This paper highlights some of the lessons learned from the experience of undertaking one particular program level change, and in supporting academic and other staff during the transition to a technology-facilitated curriculum.

The project plan: purpose and expected outcomes

The project was multifaceted. One purpose was to evaluate the experience of re-developing GDLP courses within a *WebCT* environment and, in particular, to comment on the specific mix of different types of staff (and, to some extent, student) support that experience suggested was required. The project was set up as a cooperative undertaking between the Faculty of Law and CEDAM, and was intended to provide feedback on six areas of broad interest within the broader University:

- Academic leadership and management: program and project level
- Curriculum design and course development
- Student and staff support
- Quality enhancement and quality assurance
- Technology infrastructure
- Library and student administration

Questions of interest associated with *Curriculum design and course development* included:

- what particular staff-student and student-student interactions are valued by students and support their learning? (eg what role is played by student-student discussion, peer support, cohort groups, technology mediated lecturing, role modelling, etc)
- what are some of the ways of meeting examination and student assessment requirements in technology-enabled flexible courses?
- what role is played by team- or group-work in the course design and development process and how is this best facilitated?

Some observations and findings addressing each of these questions are presented below, following a brief description of the overall structure of the project.

Project structure

Late in 2000 a project officer (learning design support trainee consultant) was appointed to a hybrid position comprising both workplace and study responsibilities. In part, the position description drew on ideas articulated by Laurillard (1993) and Walker et al., 1995) and read as follows:

> The position would suit a recent graduate who has some familiarity with the concept of instructional design...
>
> The intention is *not* so much to provide an instructional design service for areas, rather it is to facilitate areas' capacities to re-think teaching practice and re-invigorate course provision in ways which draw on instructional design concepts *and* reinforce the ethos of a research-led institution. The aim is to move beyond classical instructional design models *and* exploit opportunities opened up by new technologies. It is expected that a component of the study program will investigate the extent to which this aim is achieved, and what factors influenced the outcome.

By far the main responsibility (and most time consuming component of the workload) involved one-on-one consulting with instructors in LW who were redesigning and redeveloping courses for access by students off-campus through *WebCT*. A key principle informing the advice to instructors, is that of *alignment* of curriculum goals, student activities and assessment, explained by Biggs (1999). The project officer was required to undertake an 'online' postgraduate study program in order to gain first-hand experience of a student perspective in such an environment. The assumption was that this would assist in yielding realistic and high value consulting advice.

In addition to consulting and coaching activities for course development, there were two other significant areas of activity: program-level support, and project management. Program level support comprised periodic peer review workshops involving all LW instructors and, along with the project officer and myself. Project management involved an informal steering group comprised of the Director, LW, and myself. Project management also required substantial CEDAM-based professional support in the form of 'consultant debriefing' throughout the year, most of which I undertook. This provided a structure and impetus for continuous reflection and improvement. It yielded substantial insights into many strengths and weaknesses of both the teaching innovations being trialled by LW instructors, and our own CEDAM strategies for managing and supporting the consulting process. The more substantive 'learnings' were 'logged' in the form of a set of project-level notes compiled on a needs basis throughout the year by both the project officer and myself. These notes subsequently formed the basis for much of the internal ANU project report, which detailed a response under each of the six broad areas of interest identified above (Trevitt, 2002).

Curriculum design and educational development: some observations and findings

- *what particular staff-student and student-student interactions are valued by students and support their learning? (eg what role is played by student-student discussion, peer support, cohort groups, technology mediated lecturing, role modelling, etc)*

Technology-mediated discussions are a central feature in a number of GDLP courses. Both voice (teleconference) and text (electronic discussion boards) is used extensively.

BEST COPY AVAILABLE

Telephone interviews have been used for a number of years. These represent an authentic setting for graduate lawyers wanting to be certified to practise. Mock exercises are run requiring students to give advice to instructors acting as 'clients', and are assessable. They also provide instructors with an early opportunity to learn of any student concerns and help allay fears, correct any misconceptions about course expectations, etc, and enables students to seek any early reassurance required.

Asynchronous discussions (eg using the *WebCT* Discussion Board Tool) rather than chat room type exchanges (which require two or more people to be online at the same time) have been used very successfully. Creating a clear and relevant context (and purpose) motivated students to engage in discussion and helped ensure success. The importance of issuing specific and unambiguous instructions cannot be overemphasised. Students are not necessarily adept at picking up all the nuances about instructor expectations at the best of times, let alone when they are located remotely 'at the end of a wire'.

The two boxes below illustrate different examples of the way in which technology -enabled discussions can be employed.

In the *Skills Development* course being conducted in 2002 instructions to students read, in part, as follows.

Skills Development

Participate via the Discussion Board in sharing your reflections with other students

Post to your group's Discussion Board at least five times on five different topics (not including the compulsory topic one tutorial activity)

- I'm looking for insightful postings that demonstrate a creative approach to problem-solving in the skills area involved. I'm looking for energy in your continued professional development and a mentor approach to learning where your new found knowledge and practical experience enhances the whole profession as you share your reflections with others.
- 250 words is the recommended length.
- topics remain open for a week from Sunday night until Sunday night.

A turn as group leader (or e-moderator) summarising your group's postings for the week and posting that summary to the Main Discussion Board by midnight Tuesday of the week following the topic.

- Click below for some ideas on e-moderating:
  http://www.e-moderators.com/moderators/artonlinehost.html
- I'm looking for a 500 word reflective posting from the group leader that picks out the main threads of the group's postings and enunciates this clearly. The leader should identify common themes and weave the threads together into a posting offering a practical solution to dilemmas others have posed and some constructive critical analysis where appropriate.
- Click on calender to find out in which week you are the leader.

These instructions give students a general overview of expectations. They help set the scene, and communicate the key criteria for success. Other, more specific instructions were subsequently issued to guide the weekly discussion on each topic.

In a second course, *Civil Practice*, the use of technology -enabled discussions demonstrates a somewhat more complex – but still very workable - approach to this sort of application of *Problem-Based Learning* principles to promote student learning. This example highlights the powerful motivation associated with authentic assessment activities that have been carefully aligned with course learning objectives. In 2001, exchanges associated with this mock legal case yielded 634 messages from 23 students and one instructor during a period of approximately 8 weeks.

Civil Practice

Students in the *Civil Practice* course were arranged into groups of 3 or 4 and asked to act for the Plaintiff or Defendant in a mock case. There were 3 pairs of Plaintiff-Defendant groups. Students used different discussion groups for different purposes. For example, group members developed their case and communicated with one another using a private Defendant or Plaintiff group. (Only group members can access postings to group discussions designated as 'private'). All students acting for the Plaintiff (Defendant) were eligible to communicate with one another using a general Plaintiff (Defendant) discussion forum. In addition, they had access to discussion forums known as *The Locker Room* or *The Court Registry*. Copies of descriptions of the purpose and function of these two discussion areas offered by the lecturer in charge are given below.

The Locker Room	The Court Registry
The Locker Room is where we discuss team issues. There are a number of different elements to working effectively in teams. There will be three formal discussion periods in the locker room. One starts now (June 8). The next will be at about 10 July and the final in the last week (July 23) of the course. Your participation in all three form part of your assessment.	The Court Registry is where you need to file your documents which form part of the case file. It is NOT where any discussions take place. When your group has a document which must be sent to the other side (ie your assessable case file documents) they should be posted in here. Your opposing team will then collect the document from here and prepare their response. By the relevant date, the response shall also have been filed. Like a normal Court, documents must be filed on time. The deadline is 6pm on the day the document is due. If the document is not filed on time, the entire group gets ZERO for the item (but must still complete it so the case can continue). For this to work, everyone must take responsibility and ensure the deadlines are met.

- *what are some of the ways of meeting examination and student assessment requirements in technology-enabled flexible courses ?*

In the *Civil Practice* example above, it is clearly impossible for one instructor to read and judge the worth of each discussion contribution for assessment purposes. Instead, for the final assessment at the end of the mock case, students were asked to look back over their respective contributions and determine which four were the most important. They were then asked to write a brief account of the value of the contribution made by these four postings to the overall outcome of the 'case'. This account was then submitted for assessment. This leads to both a manageable load for the instructor and an obligation on students to develop valuable self-analysis and reflective skills.

A major review workshop held toward the end of the project addressed assessment issues. Early successes and practical options for the future identified by instructors included:

- Can we make greater use of the *WebCT* quiz tool by, for example, allocating students so many hours for an exam preview period starting as soon as they access and download the questions, and requiring answers to be submitted by the end of the designated period? This approach has the advantage that it would not require students to stay logged on while addressing themselves to the questions.
- Can we make more extensive use of the proven 1:1 telephone interview system? Students like the telephone communication – it offers opportunities for:
    - better instructor-student interaction and more immediate feedback than occurs when marking written work
    - students to enhance their performance skills in interviewing, negotiation, advocacy
    - students to raise other concerns on a needs basis – eg admission, job search, etc

  While sometimes seen as time-consuming for instructors telephone interviews may not be much worse than traditional marking.
- Project work involving team and group work encourages student interaction skills, and is valued by employers. Students work together and produce a group report that attracts a single shared mark. In order to minimise the

BEST COPY AVAILABLE

perennial 'freeloader' problem they are asked to submit individual critiques on this product (eg in the form of a succinct 'internal' memo to a 'boss' in a fictitious firm). This has the additional benefit that it encourages individuals to reflect on the group process. When designed well, group work has the potential to both broaden the skills learned and save marking time.

- *what role is played by team- or group-work in the course design and development process and how is this best facilitated?*

Prior to the commencement of this project, instructors who were rethinking curricula and undertaking course development did not necessarily work in a group or team-based fashion. Usually, courses have been taught by one (sometimes two) instructors and, subject to meeting Law profession requirements and expectations, course development proceeded within the relatively private domain of the relevant individual(s).

Our experience indicates that, with the transition to a technology -mediated study program, the curriculum design and development process increasingly involved more and more people. Structured and semi-structured discussion and dialogue has played a central role in the rethinking process. Discussion between a range of different players: between different instructors; between instructors and CEDAM consultants; between instructors and support staff responsible for management of student administration data; and between instructors, technical staff and CEDAM consultants. The systematic use of discussion and dialogue in this way is in accord with others' experiences and widely reported in the literature (eg. Schon, 1990; Laurillard, 1993; Brockbank and McGill, 1998). Schon's concept of reflection-in action, in particular, has informed the dialogue and underpinned much of the interaction between CEDAM consultants and LW participants.

Toward the end of the project the consolidation of team-based approaches to support the process of course design and development appears to be happening in an increasingly explicit and autonomous fashion (ie independent of any CEDAM input). Embryonic, self-organising groups of 2 or 3 individuals, for example, have embarked on at least two different course designs and development initiatives in the latter part of 2001. Team approaches may prove to be a key component of the emerging 'course development culture' within LW as experience mounts with the iterative process of rethinking associated with technology -mediated course design, development and provision

> 'The common interest in *WebCT* has given us a context in which to talk more about our individuals courses and identify group issues. A good atmosphere is developing involving showing what you can do and sharing options, with people readily adapting approaches from someone else's course and applying it to their own. Inevitably, approaches are put together in different ways in different courses – in ways suited to each context.' (Director, LW, 2002)

Some additional observations and findings

The experience of this project has also demonstrated that:

- a strategic leadership commitment is required from those responsible for managing degree and study programs in order to achieve such a sustained effort

> 'You can't get whole programs to change without this level of commitment. Individual courses can be changed in a comparatively straightforward way. Whole-of-program change of this sort needs a different approach – for example, the one described here.' (Director, LW, 2002)

- a campus commitment to strengthening technological infrastructure (eg installing *WebCT*) is an essential prerequisite – and an ideal trigger - for the sort of course and curriculum design rethinking (and associated course development initiatives) described here
- the transition to technology -enabled off-campus study leads to a substantial shift in instructor focus from curriculum content to process
- off-campus students need explicit support structures and communications. Students need an induction into program and course expectations: an overview of what the course is about, what they need to do and when, and what comprises the assessment.

BEST COPY AVAILABLE

- appropriate means for acquiring student feedback can involve use of telephone interviews and/or use of web-based open ended questions centred around: What worked well? What needs improvement? Answers to these questions can then be logged and managed in a small database.
- a distributed approach to the educational development (coaching) support can be highly effective (eg through an individual coach/consultant based in CEDAM but with specific area-based responsibilities – in this case Legal Workshop). Such support can be achieved with a junior position, where it proves possible to attract, identify and appoint an appropriate individual.
- a 'coach the coach' approach to support for the project officer within CEDAM appears to be essential in order to minimise the opportunities for the day-to-day 'rough and tumble' of the job to get out of hand. It also enables the capture of valuable 'institutional learning' outcomes

> 'We could not have achieved our current level of success in the transition to web-based delivery without this kind of support. It allowed us to help staff through the intellectual and cultural change, and saved us from foisting unworkable courses on students.' (Director, LW, 2002)

A wide range of ongoing issues remain. Those concerning the rethinking of curriculum include:
- determining practical and timely ways to keep abreast of new and successful teaching approaches being developed in the context of web-enabled off-campus course delivery
- how to assist instructors to find time for the continued ongoing course design and redesign, and student activity planning work
- the desire to streamline the assignment submission process using *WebCT* tools
- identifying what additional skills instructors can/should develop either individually or as a team in order to continue to strengthen the program

Concluding discussion

The project experience described here is in broad accord with that articulated in the opening quote by the US Council of Graduate Schools. The shared approach to project leadership involving both 'top-down' and 'bottom-up' strategies accords with Johnson's (1997) recommendations about the requirements for effective educational change. Quality of the student learning experience was maintained by:
- developing and engaging in a group or peer 'review' process of curriculum redesign and teaching review;
- acquiring, interpreting and acting on student feedback in a timely way; and
- using external facilitation by educational development staff to support these two processes.

A sustained commitment to an evidence-based approach to course redesign and redevelopment was achieved. Cyclically acquiring, interpreting and acting on student feedback enabled the transition to a successful technology-enabled curriculum to be achieved over just three or four iterations of course design, development and implementation. Given the magnitude of the conceptual change demanded of teachers undertaking such ventures, we suggest this is a very reasonable number of re-development cycles.

Provocatively, our experience suggests that the use of an internal consultant working as a 'coach' (and supported by an appropriate 'coach the coach' process) is a cost-effective means to support the demands to rethink curriculum. At first glance, this is a counter-intuitive outcome. However, when we consider what is now known about the nature of 'deep' learning (eg Biggs, 1999), and the central role played by conversation and dialogue in achieving conceptual change, and the importance of conceptual change to the curriculum rethinking process, then this is not necessarily an unexpected outcome after all. Perhaps the real issue concerns the extent to which it proves necessary (or not) to continue to provide external consulting support now the transition is mostly complete. Equally important is the question of how flexible a course should be: When is a course in danger of becoming too many things to too many people? At this stage it is still too early to offer an evidence-based opinion on these important points.

Abstract: Today, faced with the problems of global competition, increasing costs, and complex production engineering, a company can only be successfully managed if the employees are motivated and highly qualified. To cope with this demand the new educational scheme for cost-effective retraining, lifelong learning and distance education at the workplace should be introduced. This paper describes the developed Web based Intelligent Training System used in the Bosch WebTr@iner product range. It details how Java simulation, virtual reality modeling and animation can be used in a complementary approach to teaching complex industrial processes and systems in a cost-effective, rapid and interesting way on the global scale.

Introduction

Over the last decade, a dramatically increased rate of change in business has been observed. Companies are struggling to keep pace with new competitors that are introducing products at an incredible rate. The technological innovations and cycle are becoming shorter and the current technology will be obsolete and replaced by new advanced technology within a few years. But this increased rate of product introduction and the shorter technological cycles has created a huge problem. First of all there is demand for a higher level of knowledge to cope with the "scientification" of industrial branches based on advanced technologies, which should be provided for greater number of employees. This demand is even stronger in correlation with the fact that technology is getting younger simultaneously as workforce is growing older and globally dispersed.

Specifically, companies are being challenged with how to enable employees and the channel to sell and support the products that are flying off the assembly line. As a consequence of this fast development, there is no doubt, that retraining and lifelong learning of engineers, technicians and workers from industry is becoming a necessity (Schmockel, 1998). To maintain their innovative forces in the future, highly qualified experts with a multidisciplinary background, experimental skills and social attitude must be educated (Donovan, 1999).

The ever-growing importance of knowledge and greater numbers of people being educated and trained at the high level has increased the responsibility of educational institutions. Governments and industry are under tremendous pressure to convey more and more knowledge and skills at ever-faster rates to growing number of persons in need of education and training. But the costs involves for such rapidly growing demand is reaching proportions, which can no longer be financed even by the industrialized nations with conventional educational and training methods.

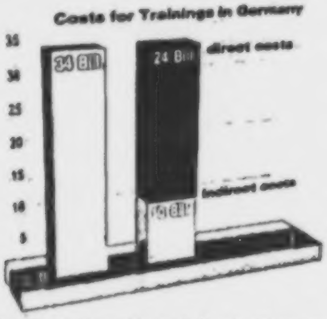

Figure 1: Costs for training in Germany

The diagram of Fig. 1 (see Hyperwave, 2000) shows how the total expenditure for training in Germany compares to the direct and indirect costs of training. Of the billions spent in this area, on average only about a fifth is spent on costs that directly relate to the training course. In fact, it is indirect costs (travelling and accommodation expenses for example) that make up the rest of the outlay. Often, the hidden cost of temporarily replacing staff is overlooked. Worse, staff may not actually be replaced during the time they are absent for training. The business is, therefore, operating in a much less efficient way.

What these estimates show is that traditional methods for training are not proving cost-effective. Although the diagram is for a specific country, it is highly probable that the situation is the same in practically any location.

To face the above-mentioned topics and develop new paradigms for learning, the contents, methods and forms have to be changed to fulfil the growing personal needs for a higher level of knowledge in new specialization and skills. To cope with this demand the new educational scheme for cost-effective retraining, lifelong learning and distance education at the workplace should be introduced.

The e-Learning tools accessible via Internet/WWW technologies create a very good environment to solve this complex task. By providing a solution that overcomes the challenges of proximity and time, e-Learning is a vital component in succeeding in business today. Wolz (see Wolz et al., 1997) have investigated the use of computer-mediate communications in educational environment. Maurer (Maurer and Dietinger, 2000) have described how modern WWW systems support teaching and learning.

Considering these facts, it is particularly in the automation sector that tailor-made vocational and specialized training has advanced to become one of the decisive criteria for success. And this is where Bosch AT-didactics comes in with its unique training program (Bosch AT-Didactic, 1999).

The paper describes the structure of the developed Web based Intelligent Tutorial System (ITS), used in Bosch WebTr@iner product line. It details how Java simulation, virtual reality modeling (VRML) and animation can be used in a complementary approach to teaching complex industrial processes and systems in a cost-effective, rapid and interesting way on the global scale. The target audience, for which the WBT is designed, is sales personnel and technicians. Through the WBT they should gain a better understanding of the advantages of the range, which should contribute to improving the sales for the sales personnel and technical knowledge for the technicians.

Learning Objectives

It has been the authors' ambition to design Web based courses in accordance with the model for "independent learning", with a particular emphasis on the interaction with the course material. The Web based trainers should guarantee opportunity for:

- Life-long, independently responsible learning;
- Motivated learning;
- Self-determination/autonomous learning (learning time, learning methods, learning tempo and possibly even subject matter have to be determined to a grate extend individually)
- Training on Demand (Learning will no longer take place only in the classroom or the laboratory. The training will go to the trainee, to his workplace, his office in the company or privately at home.)

Experience has shown that the effective development of training concepts and materials require a clarification of various learning objectives. It is useful to distinguish the different groups of goals since it is important that each group be matched with the appropriate didactical procedure (IWL Martens, 1999). We distinguish between learning objectives, in which experiments and hands-on experience are of prime importance, other learning objectives for which a visualized and clear presentation is decisive, or learning objectives that depends on video or films to reach the feeling of the learner.

Multimedia program is designed to reach the following learning objectives:

- Developing positive attitudes towards personal effectiveness;
- Recognizing the possibilities of influencing difficult situations;
- Accepting difficulties as challenges;

The learners have to be trained with extensive hands-on experiments to strengthen further understanding of theory. The idea is to illustrate all theoretical concepts with examples selected from real-world applications, in order for learners to benefit from the practical experience and to help them understand links between theory and practice. The experience side of e-learning should address factors including:

- Engagement: How will we get the learner fully engaged?
- Curiosity: How will we harness the power of curiosity and exploration?
- Simulation and Practice: More powerful simulation and practice opportunities?
- Action Learning: Simulators that trigger action learning and align with workplace challenges?
- Intensity: How can we create high intensity, memorable learning experiences?
- Assessment and Feedback: Help the learner to gain a better sense of their knowledge gaps?

In using interactive media the learner is required to repeatedly solve complex tasks and thus is actively involved and at the same moment is demonstrating mastering of material. Further, the results of short follow-up tests should show to what extend the learner is personally affected by the content of the presented material. Self-evaluation will make progress visible to the learner, and help to decide when to proceed in the material.

The learning methodology, implemented in the WebTr@iner, is designed to maximise the impact of modern multimedia technologies and human-computer interaction to achieve high quality training, which is attractive to the student. The approach used aims to place the onus of learning on the students' own initiative. Based on his/her own knowledge and experience, the student is able to choose the appropriate route through the course material, and in turn this improves his/her motivation during the learning process. This requires the course material to be structured into essentially independent modules, freely accessible in whichever sequence is desired.

WebTr@iner Series

The WebTr@iner series consists of several educational courses, which have been developed in Web technology. All modules are directly accessible by the WWW browser. The network version may be directly run on a Web server, so networked learning and distance learning via Internet and training servers has become reality. The WebTr@iner is suitable for autodidactic learners who want to familiarize with a subject as well as for trainers aiming at lively multimedia-supported classes.

Several e-Learning tools are available: Hydraulics-Basics; Hydraulics-HS2, Electro Hydraulics; Pneumatics-Basics; Pneumatics-Controls, Continuous Control Hydraulics. All systems are modular in concept and can therefore be directly adapted to specific requirements. They can be extended and combined with each other at any time and in accordance with the learners' wishes. By personalization of course content based on the personal skill of a targeted individual Role Based Training is ensured.

Above all, effective learning is based upon the quality of the training and the training system as well as upon practical exercises. The varied design of the WebTr@iner series including quality images, graphics and sound-videos ensures an interesting training course and facilitates knowledge transfer. Trainers comprise an intuitive user-friendly interface, a convenient navigation system; a modular architecture; a proper ratio of text material and animations.

An environment for *learning by doing* on the basis of developed interactive tools and *learning by discovering* based on the simulation of real systems are provided. The developed Web trainers offer a virtual classroom experience that combines the benefits of traditional classroom training with the flexibility of e-**Learning** in order to increase learning with high moment of teaching value.

WebTr@iner Structure

ATTENTION: IF THE WEBTR@INER YOU ARE U
ON A NETWORK SERVER OR ON AN INTRA/INTERNET SITE,
DOWNLOADING VIDEO CLIPS MAY TAKE A FEW MINUTES!

Figure 2: Basic information page of the WebTr@iner

All tutorials have a common structure (Fig. 2) build around the aim to offer a learner-centred environment, in which the learners are actively involved in the learning process. Generally the WebTr@iner structure has **Learning**, **Practice** and **Test** sections. Advanced Web technologies and methods, which encourage learners participation are used to the maximum extend in all sections.

A video clip shows practical application of the considered component or system in industry or real life.

Mode of operation is illustrated by 3D animated model. Animation is a particularly valuable technique when it illustrates phenomena, properties, and any topics, which cannot be effectively described by static published lecture notes. High degree of animation and interaction are of crucial importance to the presentation. Interactive animations provide insight into the inside of component and illustrate its functionality.

After the consumption of the individualized training unit, the trainee gets the chance to practice the newly obtained knowledge. A **virtual reality** play model is provided to visualise the functions and flow characteristics of hydraulic or pneumatic components. Virtual reality models of components are a good opportunity to bring more transparency into dynamic processes occurring into the component during its operation.

BEST COPY AVAILABLE

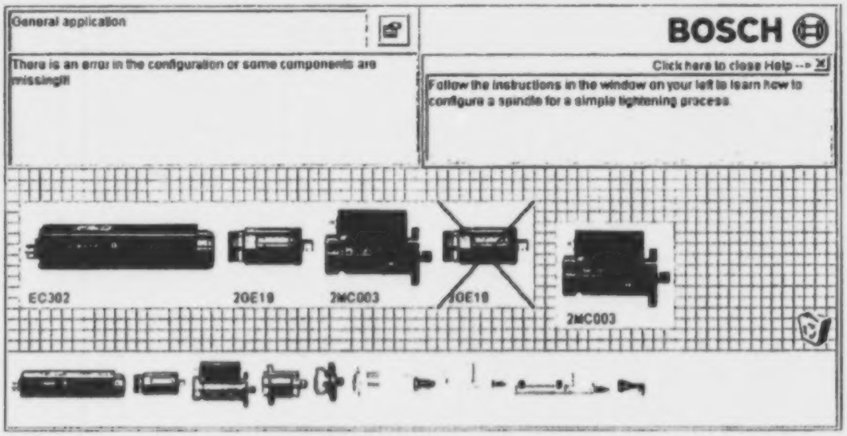
Practical training via **interactive simulators** can contribute considerably to an easier and deeper understanding of the learning material. In systems simulations, the trainee may apply the newly gained theoretical knowledge to entirely risk free practical solutions and trace the interaction of components. **Guided experiments** are also provided in which learners should follow step-by-step instructions of virtual tutor. Correctness of learners' actions is checked at every step.

The evaluation of the gained knowledge and assessment of the level of understanding are the natural accompanying measures of the self-learning process. **Tests** are a special kind of interactive learning. The test questions are designed in a way to illustrate as clearly as possible what the learners are expected to learn and which aspects are more important than others.

Interactive Tools

A better understanding of the physical, electrical, and mechanical properties is strongly desirable, because of the increasing complexity of today's industrial applications. This is not possible without hands on experience. For this reason practical training is very important. The skills obtained through problem solving are a strong contribution to the introduction of learners to the behavioural patterns of today's industry.

Assembly Unit



General application

There is an error in the configuration or some components are missing!!

Follow the instructions in the window on your left to learn how to configure a spindle for a simple tightening process.

Figure 3 Java based interactive assembly tool

The assembly unit is developed as a general-purpose interactive tool for assembling different systems from the predefined set of components. Users can interactively choose every one of components and move it to the right place in the system, which should be assembled. Checking facilities and context sensitive on line help are provides as well.

The tool has three regimes called "show me", "guide me" and "try me". The first shows the right way of assembling the system being on consideration as well as sequences of user actions that should be done for obtaining such result. These sequences include choosing appropriate component for placement, moving it to the right position and placing there, choosing the next one etc. The second regime like an intelligent "virtual tutor" guides users step by step during assembling. In this regime incorrect actions are prevented and the user can start placement of the next component only if the previous one has been placed to the right position in the system. The wrong component and the wrong position are disabled for using. The third regime allows for free placement of every component at every position in the system. The Check facility is intended to show users correctness of their actions. All obtained errors are marked on the screen and an appropriate report is provided to the user. Fig. 3 shows the user interface of the interactive assembly tool and the result from checking of the current system configuration.

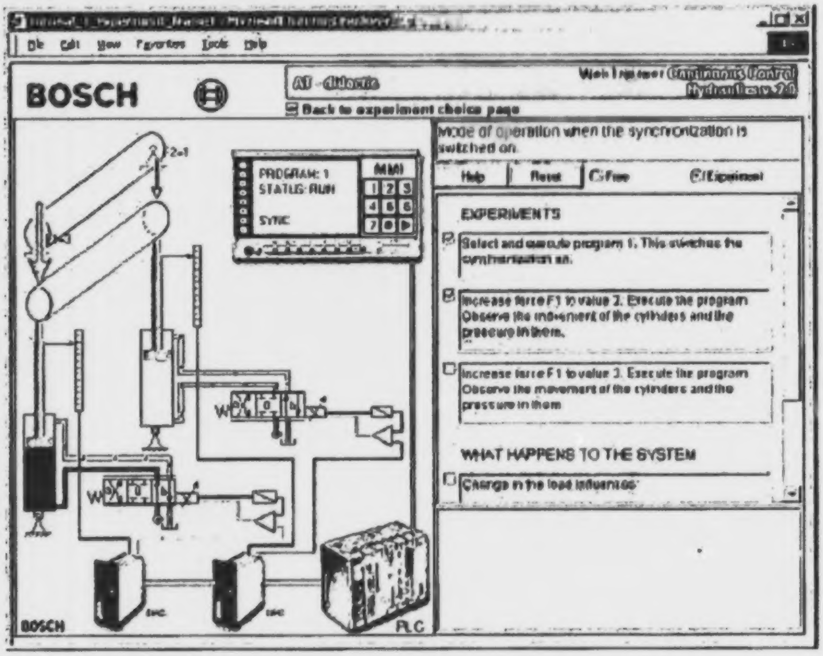
System Simulators

Technological progress has led to new approaches to complex production processes. Hybrid systems with open system architecture have replaced traditional hydraulic, pneumatic and electric systems. They link and control all system components. Such systems are mainly used in high technology environments. Their proper operation need appropriate maintenance staff, which should have a firm understanding of the whole system.



Mode of operation when the synchronization is switched on.

☑ Select and execute program 1. This switches the synchronisation on.

☑ Increase force F1 to value 2. Execute the program. Observe the movement of the cylinders and the pressure in them.

☐ Increase force F1 to value 3. Execute the program. Observe the movement of the cylinders and the pressure in them.

☐ Change in the load influences:

Figure 4: Java based system simulator

It is very important learners to have opportunity to obtain hands-on experience working with the system. It is not common practice in industry to stop technological process and to use production system for education. This is also very risky, because using product equipment by unqualified learners can easily lead to personnel hazards and material damages. For this reason interactive simulators are very useful for training. They provide the learners with an easier and better understanding of complex problems using simulation to animate various properties, operational principles and phenomena.

Fig. 4 shows an interactive Java based simulator of one Bosch continuous control hydraulic system with decentralized peripherals. Programmable logic controls (PLC) ensure predefined functionality of the whole system and each individual component. The system can perform different operations depending on the program incorporated. By clicking on the man-machinery interface (MMI) unit users can change the program and observe the signal sequences, interactions between different components in an automated system, sensors reaction and corresponding action of the robot and other equipment in the production line. All dynamic processes are visualised by changing colours for signal sequence, sensors and different fluid pressures. Animations are used for a products flow on the product line, robot hand movement and cylinder rod movement for current forming operation. Changing the program will change the PLS command and the same equipment will perform quite different operations. For educational purposes the main component of the system appears in the screen in the same manner as in real production process.

Intelligent "Virtual Tutor"

In the previous section the so-called "free experiment mode" of the interactive simulator was considered. "Guided experiment mode" is also provided. To increase teaching value in the tutorial an intelligent "virtual tutor" is used in guided experiments. The idea is to stress learners' attention on important topics, on specific features of the system, on critical operations or on required sequence of operations, which should be performed for guaranteeing error-free mode.

There are two experiments per tutorial, which force learners to follow step-by-step instruction to complete the experimental task. This "virtual tutor" not only guides learners, but at every stage checks if they have properly performed the task. If not, the next step is disabled. On line help is also provided on request.

Fig. 4 illustrates the free and experimental modes of the simulator. In free mode all the controls are accessible. During the experimental mode all controls are disabled except the particular one needed for that task.

After successfully completing the guided experiment the learners are requested to answer two questions in order the "virtual tutor" to check if they have understood the system's mode of operation. Learners obtain on-line feedback of correctness of their answers.

By becoming an active part of the learning process, the learner is involved in a self-organised discovery process. Thus he/she can learn not only the basic properties and processes, but also acquire a better and deeper understanding of the analysed subject.

3D Virtual Reality Models

Virtual Reality Modelling Language (VRML) is used for 3D representation and simulation of dynamic technological processes. The created virtual environment gives the user opportunities to play and experiment risky-free with complex machinery, to take a look inside the different components, to learn about their controls and adjustment procedures.

Most of the 3D models have at least two different representations, each one with a different level of details. Depending of the proximity of the user to the component, a more or less detailed model is visualized. Cross-sectional models help for better understanding of how the components work Components can be rotated and examined from any direction; the paradigm of "Walk" and "Fly" is used to navigate in a complex environment. A mathematical model is used for calculations of output pressure and flow rate according input values and user presets and adjustments at run-time. This permits complete hydraulic/pneumatic schemes to be composed and simulated by linking together inputs and outputs of different components.

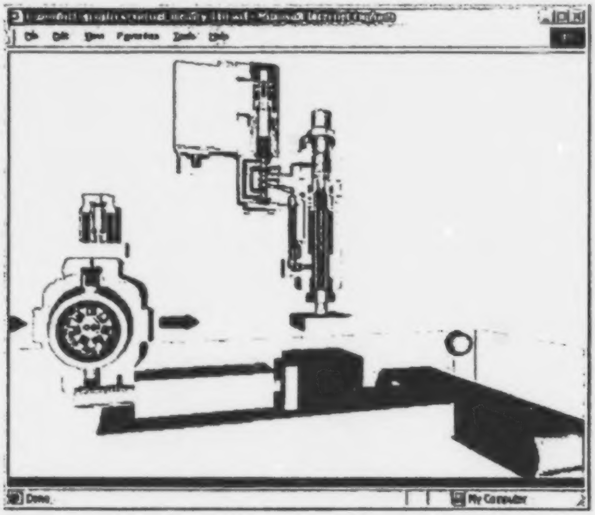

Figure 5: VRML 3D model of the decentralised hydraulic peripheral system

BEST COPY AVAILABLE

Fig. 5 illustrates an automated system composed of hydraulic press, robot application and a transfer system. The changes of flow rate and pressure in a continuous controlled hydraulic system with a **variable displacement pump,** 4/3 Direct Control Valve (DCV) and a double acting hydraulic cylinder are examined. The model helps to illustrate the relationship between needed press power and displaced volume by the hydraulic pump.

A program, simulating a Programmable Logic Controller (PLC), drives the action sequences from the press, robot and the transfer system. The VRML model and the Java-based PLC Simulator are linked via the External Authoring Interface (EAI).

This approach allows for the creation of free-programmable virtual environment. It can be used for simulation of different technological processes only by changing the program, interpreted by the PLC Simulator.

Conclusions

Training and enhancing the skill and expertise of personnel is imperative. But the complexities of today's fast paced business environment make effective training and continuous learning a challenge at best. That is where **e-Learning** will provide its benefit.

This paper describes an intelligent interactive **e-Learning** system for teaching hydraulics and pneumatics. In addition to theory, it includes:

- Video clips illustrating the basic application of the system;
- Many animated pictures showing components' mode of operation;
- Virtual 3D play models of the basic components;
- Interactive assembly unit, for system assembly from predefined set of components;
- Interactive system simulator demonstrating different modes of operation;
- Intelligent "virtual tutor" guided experiments
- Self-tests.

The main advantages of the proposed intelligent WebTr@iner can be summarised as follows:

- The teaching method used illustrates complex processes in an easy, clear and attractive manner;
- It takes into account the different levels of knowledge of students starting the course;
- As an Intelligent Tutorial System it reacts to the students' capabilities and mistakes;
- It is quickly accessible, easy to update and distribute;
- Widespread geographical areas will not cause a logistical problem.
- It provides a time and cost effective training of users;
- WebTr@iner is available in various languages;

The implementation of the Intelligent Training Courses and modules on the Internet/WWW allows the sales personnel and technicians to work autonomously at any time and at any site. Together with the didactic department of Bosch Automation a system was developed to easily train staff worldwide. The ITS approach offers scope of application in training curricula that similarly require complex and global solutions i.e. corporate management or sales training as well as electrical and mechanical engineering. Distance education through network offers tremendous opportunities not only for continuing education but also for education in general to break the barriers of place and time that otherwise limit access to teaching.

Abstract. The aim of this paper is to demonstrate how an evaluation framework was developed and implemented in order to support goals of an e-learning university. The paper will discuss the aim of assessment to support institution-wide e-learning goals, the benefits and challenges of this approach to assessing the development of content for e-learning, a description of the evaluation framework and the assessment tool GUIDE (Guided Instructional Design Evaluation), and the results based on implementation for the development of graduate and undergraduate programs.

1.0 Introduction

We introduced an evaluation framework to support assessment of the development process for e-learning content. The aims of the framework are: a) implementation guidelines for the development process that based on best practices in pedagogy; b) the strengthening of participants' ability to evaluate their own and others development efforts; c) creation of effective assessment practices; d) dissemination of information including information about our collective development strengths and weaknesses.

The larger aims of the evaluation framework were to emphasize the development of learning and support staff, ensure formative assessment and feedback to continually improve our processes and procedures, and to support an institution-wide mission and goals for learning, resulting in design strategies to accomplish these goals.

2.0 Supporting Institutional Goals

In the case of Technical University of British Columbia (TechBC), the assessment of the development process is strategically shaped by the need to support institutional goals of effective learning, learner-centered learning, and the effective use of technology.

"As an evaluator you assess what is important, thus influencing educational processes and products, and moving these closer to a prescribed level of quality. In any organization, quality is ensured by strategic assessment practices that acknowledge, through the factors that are examined, the mission and goals of the organization." (Orden, 1982:23)

The mission of the academic program can best be described as creating an accessible and effective learning environment. The use of evaluation of the development process strives to achieve and support the mission and goals of the institution within the curriculum and its delivery.

2.1 Effective Learning

Learning effectiveness is a key composite measurement of institutional, program, and module/course level assessment results. For example, at TechBC, following scalability factors discussed by Tony Bates (Bates, 1995), the development clusters, and the assessment phases of the development were seen to be central supporting tools of assessment in relation to delivery models, and instructional design.

The renewed emphasis of the learning environment and the role of instructional design in e-learning require support of assessment methods. The assessment of the development process supports and ultimately validates effective learning activities and delivery environments.

2.2 Learner Centered

Policy directions of the use of evaluation models aimed to re-enforce good assessment practices helped achieve the goal of learner-centeredness as described by Patricia Cross, "...students and their learning should become the focus of everything that we do. From the instruction that we provide, to the intellectual climate that we create, to the policy decisions that we make..." (Cross, 1998).

2.3 Effective Use of Educational Technology

Effective use of the technology in learning is best achieved by ensuring the application of the technology is considered to be interwoven with learning goals, learning and instructional design strategies, resources and logistics. The assessment of the development process and in particular the Quality Circles support this approach and aid in ensuring its successful implementation, becoming a critical component in support of technology and learning goals.

3.0 Benefits & Challenges

3.1 Effective curriculum implementation

In relation to curriculum planning, the goals of TechBC, are to be interdisciplinary in learning strategies and knowledge sharing, and to provide a quality consistent learning environment that nurtures the use of educational technology and is learner centered, regardless of the discipline. Cross-program implementation of the development process supported the curriculum planning goals.

TechBC was faced with a need to look for efficient, scalable methods of developing large numbers of courses – often in new formats and using new technologies – while continuing to meet high pedagogical standards. Some institutions have approaches that are rich in the support and implementation, but too rigid or not applicable in large-scale production (Leacock, et al, 2001).

Scalability in the development process is achievable through the embedding of learning technology. The process of embedding learning technology is not insignificant (Laurillard, et al., 1993). One reason for this is the considerable range of skills that need to be acquired if embedding is to be carried out in a professional way (Phelps et al., 1999).

Early research into the requirements for the design tool showed that there was clear need for support in the process of designing or redesigning courses, in order to take advantage of the opportunities provided by learning technology. For effective use of technology practitioners should be given training, professional development and continuing support.

The reality of having faculty with different skill sets, all knowledgeable in the use of technology, but a wide range of expertise in educational technology, curriculum knowledge, and course development needs to be addressed. Defined development processes, project management and an integrated assessment framework aids substantially in identifying the skill gaps of the people undertaking the task (Conole and Oliver, 1998).

3.2 Effective Management

The delivery of the academic programs aimed to be portable and scalable. Central to the issue of scalability is the need for assessment to support a learning practice that is understood in discrete elements (subject knowledge, pedagogical expertise, multimedia skills, assessment techniques), and understood as a team effort [CVCP, 2000]. At TechBC, inter-disciplinary cluster groups made up of faculty and support staff in assessment, instructional design, media development, research and project management ensured a high level of quality and effectiveness was achieved in the academic programs.

The assessment structures embedded in the development process support these outcomes and are integral to them. This approach to development allows for greater portability and scalability of the online curriculum.

3.3 Cost-effectiveness

Effective resource management is critical to the successful implementation of online learning. From an academic planning perspective, in order to support successful resource management, the components of intended learning environment must be fully formalized.

If the formative approach to assessment improves the quality of delivery, this ensures less cost at revision time.

4.0 Evaluation of the Development Process

There is literature that reflects on the use and goals of putting together an assessment strategy in the development phases of the project. Most of the time the guiding principle is formative (Calder, 1994); monitoring the development of the product at each phase to ensure quality and achievement of the objectives. In other cases the guiding principle is accountability. Yet, the most common approach is summative, measuring the final product against specific criteria.

Bates (1997) defined the following criteria as determinant factors of quality of an online course: a) content, b) media production, c) instructional design, d) project management, and e) delivery (Bates, 1997).

Most institutions concentrate their assessment efforts on the assessment of the course delivery, using learners' comments as the most common approach for accounting of quality in online courses, and as information required for revisions.

Course delivery has shown to have great dependencies on the quality of the development. The relationship lies in the idea that the quality of the delivery depends on the foundational development work put into the course -- the quality of the content itself, the value of the media production selected, and the skill of the content experts as an instructional designer and project manager. In addition to the support of resources and clear processes, quality development relies on an assessment framework to identify gaps and insufficiencies. It is clear in an elearning context, that reliability and quality of the outcome must be assured prior to delivery to learners, and not during.

Specifically, the purpose of assess the course/module development process are:

- To introduce a process for formative review and assessment of the development of the program and the course/modules.
- To implement guidelines for the development process that entrench good pedagogical practices.
- To invoke effective assessment practices.
- To effect management guidelines to ensure quality, fairness and validity, and serve the university's philosophy of innovation.
- To assess effective use of resources and identify skill gaps.

4.1 Stages of the development process:

The development process has five phases: 1) Planning phase, 2) Specification phase, 3) Design phase, 4) Production phase, and 5) Post- production phase.

Each phase has specified deliverables (Belfer and Nesbit, 2001). Institutionally, these phases are coordinated and initiated through an academic workflow process that ensures effective strategic goal setting, design, resource allocation, and implementation of all academic projects.

I. Planning (occurs prior to development cycle)

The purpose of this phase is to plan all or part of an academic program by specifying the program marketing strategy, student characteristics, modules, module objectives, and the pre and co-requisite relations between modules. It also includes creating a plan, assigning roles and responsibilities, such as project manager, membership for the different development clusters, and timelines.

II. Specification (2 weeks)

The outcome of the specification phase is information such as, course name, credit weight, course description, unit names, sequence of units, unit learning objectives, and brief descriptions of learning objects and activities planned for each unit.

The specification phase is very important in the development cycle. During this phase the high level instructional design is specified.

Developers concentrate most of their time doing research to determine the scope of the development, the level of the content, existing textbooks, learning objects, and educational technology options. Upon completion the developers expectations and/or requirements are measured against the existing delivery and evaluations models.

All the specifications are revised by a peer group responsible for contrasting specifications against program goals and system capabilities, and a determination is made at that time on whether the development is to proceed.

III. Design (4 weeks)

The purpose of this phase is to create and publish a prototype of the course in the online learning environment. A unit is regarded as approximately one week of learning time. The prototype includes learning objectives and outlines of web presentations, assessments and learning activities. An instrument called Guide (Guided Instructional Design Evaluation) is used in this phase to assess objectives, delivery model, assessment activities, learning activities, workload, teamwork, learning resources, and the level and quality of the content and web presentation.

IV. Production (8 weeks)

The purpose of this phase is to complete course development by creating learning objects and completing all course authoring and editing tasks. This phase is carried out by the course development team together with educational technology support. GUIDE is used in this phase to assess media elements, and to re-assess learning resources and the level and quality of content.

V. Post-Production (2 weeks)

The purpose of this phase is to ensure the material reads well for the web, outline recommendations for future development of the course, and develop the course delivery plan (e.g. instructors' notes).

4.2 Assessment Process

Table 1 describes the objectives and both formative and summative assessment procedures that would be applied at each stage of the module development process.

4.2 Design Phase: Quality Circles

Quality Circles was one of the most successful parts of the assessment process for meeting its objectives and building on the formative aspect of assessment. Approximately two months into the development cycle. A team that consisted of experts in instructional design, assessment, module content areas, and representatives from the academic planning and academic operations areas (Quality Circle Team) would review a prototype unit.

The Quality Circle team uses Guide to evaluate these prototype units against pre-defined criteria that addressed the learning objectives, assessment strategies, application of delivery models, learning activities, web presentations, interactivity, learner workload, content, balance between team-based and individual work, and match between the resources available for development and the needs of the module. Representatives from the Quality Circle team then meet with the developers to provide feedback.

In many occasions developers commented on the value of the process. Being timely feedback, the opportunity to share ideas, and cluster and interdisciplinary collaboration the key elements that motivated this comments. In a short period of time a great amount of data is gathered, analyzed and synthesize to provide developers with substantial feedback their at a critical juncture in the development process (Leacock, et al, 2001)

4.3 The Instrument: GUIDE

GUIDE (GUided Instructional Design Evaluation) was created in response to the need for an efficient, reliable and comprehensive instrument capable of supporting the formative assessment of all courses offered (Belfer and Nesbit, 2001).

Drawing from literature on instructional design (Diamond, 1998; Dick & Carey, 1996) a set of rubric-based items applicable to TechBC's modular learning structures and delivery models were created. The development and resulting format of the instrument is similar to the Primary Trait Analysis (PTAs) described by Walvoord and Anderson (1998). PTAs are constructed by identifying components or traits of the products to be assessed then creating a scale for each component and annotating each level of the scale with a descriptive rubric.

Several instructional design components expected to be present in TechBC courses were identified and few items for each component were determined. Table 2 shows the components and the number of items created for each component.

Table 2. Instructional Design Components Assessed by GUIDE.

Component	Number of Items	Component	Number of Items
Learning Objectives	4	Learning Resources	4
Delivery Model	3	Teamwork	4
Assessment Activity	5	Workload	3
Learning Activities	3	Media Elements	9
Content	8	Resources	4
Web Presentation	7	Support for Development	10
Editing	5	**Total**	**68**

For example, the Learning Objectives trait component was broken down into 4 items: Taxonomic Level, Clarity, Fit with Assessments, and Fit with Activities. Table 3 shows the item for Learning Objective Clarity.

Table 3. The Learning Objectives Clarity Item.

Objectives	Strong	Satisfactory	Weak	Absent	Score
Clarity: Objectives are clearly defined.	The objectives are clearly defined.	The objectives are somewhat clearly defined.	The objectives are not clearly defined.	The way the learning objectives are written does not provide information about the expected outcomes. **Or** No learning objectives are specified.	

5.0 Results

The formative assessment structures focused on product and process review, not performance evaluation. By structuring the review to focus on the deliverables, we reduced the anxiety and defensiveness that can be associated with personal evaluations. Instead, the emphasis was on working together to create the best modules possible, and the outcomes have supported this approach.

The most rewarding part of this process was seeing a marked improvement in understanding of instructional design concepts amongst developers over the course of the development cycle. Feedback that showed how these concepts apply to the work each person was doing provided developers with tools for current and future development projects (Leacock, et al, 2001).

The summative assessment structures mainly relay on accountability measures that help keep the developers on schedule with expected milestones and inform the community of the accomplishments obtained.

The development process is based on a cluster approach that enriches the products by providing developers with venues for collaboration and sharing. An emphasis on the development of learning and support staff, formative assessment and constructive feedback enable us to continually improve our processes and procedures to achieve our goals. It has created an institution-wide acceptance of the mission, goals and design strategies required to accomplish these goals.

Lessons from An Action Research on Project-based Learning in a Web-based Learning Environment

Chien-hsing Wang

National Changhua University of Education
Taiwan, R.O.C.
chwang@cc.ncue.edu.tw

Abstract : This study investigated issues on the project-based learning (PBL) approach with web technology. Action research methodology was employed for the investigation. Data included online discussions, an online questionnaire, and the transcripts of face-to-face interactions. Content analysis was used for data analysis. The findings showed that students required more scaffolds to become active learners and assume their learning responsibility. Their abilities of searching information, usingtechnology, and keyboarding also influenced their learning and participation. In addition, a powerful, stable, learner-centered system was needed to implement project-based learning effectively. Finally, the instructor's skills in dealing with emotional issues are important to successful online learning.

Introduction

Project-based learning has a potential to overcome inert knowledge. With PBL, learners have opportunities to foster their skills of inquiry, critical thinking and reflections by involving themselves in an authentic, complex learning context. Consequently, PBL serves precisely the need of connecting knowledge to the contexts of its application. However, to implement PBL requires a resource-based learning environment that augments collaboration, communication, reflection and authentic assessment. Web technology enables educators to create such a rich resource-based learning environment. Therefore, he paper intended to discuss critical issue in implementing PBL in a web-based learning environment from a teacher-researcher perspective. First, the rationale for the course and research design is presented, then, the research results and finally the reflection on teaching based on literature.

Rationale

It is a necessity for educators to arrange the kind of present experiences that live fruitfully and creatively in subsequent experiences according to Dewey (1953). Educators have the responsibility of being aware that environments can shape student's actual experience and recognizing what surroundings are conducive to learning experiences leading to growth. School education must give each present experience a worthwhile meaning, and should be an ever-present process if knowledge application in the real world is expected.

Students are motivated to deepen their understanding of key concepts and sharpen their skills if they perceive the apparent connection between what they learn in school and its potential uses of that knowledge in real world situations (Steinberg, 2000). One goal of project-based learning (PBL) is for students to learn, and be able to use formal knowledge in an authentic and complex setting (Barron, Schwartz, Vye, Moore, Petrosino, Zech, Bransford, & the Cognition and Technology Group at Vanderbilt., 1998). PBL is intended to combat the inert knowledge and to enhance learning by engaging students in authentic, real world task as that in professional situations (Guzdial, 1998; Laffey, Tupper, Musser, & Wedman, 1998; Poell, Van Der Krogt, & Warmerdam, 1998; Schwartz, Brophy, Lin, & Bransford, 1999; Steinberg, 2000). However, PBL also challenges students and teachers and overwhelms the cognitive support structures found in contemporary education (Laffey et al., 1998).

Web-based instruction is an application of a repertoire of cognitively oriented instructional strategies implemented within a constructivist and collaborative learning environment, utilizing the attributes and resources of the Web (Relan & Gillani, 1997). According to Relan & Gillani, the assumptions of WBI are as follows: (a) the learner has access to the Web at all times and is allowed to explore it in a self-determined or guided sequence, (b) WBI would function best in a constructivist environment, (c) teachers as a facilitator for finding, assessing, and making meanings from the information discovered from a variety of media, and (4) learning occurs in an interdisciplinary fashion without regard to the attainment of learning objectives within a fixed time frame. Therefore, this study was to implement PBL in a web-based learning environment on the course of Introduction of Education.

Research Design

Course Design

Based on the aforementioned rationale, the course design for this study was anchored in the issue of network-café, which was a nation-wide hot issue at the time. Each group conducted a self-directed project to present their perspective on the issue based on the knowledge domain they chose (ex. parenting, educational psychology, etc.). The first three weeks were devoted to the introduction of the course, the web-based learning environment, and the Software of Netmeeting in face-to-face classroom settings. The following five weeks were online roundtable meetings on the issue of network-café focusing on specific topics (e.g. family relationship). There were students-teacher online group meeting during the 9th and 10th week. In the week of midterm, the software of Media Master Recorder was taught to two representatives of each group in a face-to-face setting for their project purpose. Students submitted their project in a written format at midterm and critiqued peer's work online. Then, they were asked for revising their work based on both their peers' and the teacher researcher's feedback. Finally, they submitted their project in the format of oral presentation clip with text for the grade. A face-to-face self-evaluation meeting was held in the last week. An online questionnaire was administered after the final meeting during the same week and the following one.

Subjects, Data Collection and Data Analysis

Forty-six students participated in this study. Most were freshmen majoring in Special Education except for two freshmen majoring in Guidance & Counseling, two graduates in Special Education and one graduate from Science Education. Data collection included student-teacher interactions via online synchronous discussion and e-mail, face-to-face meetings, online roundtable meetings, online asynchronous discussions, the online questionnaire, and the transcript of self-evaluation meeting. Content analysis was used for data analysis. The framework of "teaching presence" by Anderson, Rourke, Garrison, & Archer (2001) was used as a reference to analyze the data mentioned above.

Results

The results showed that the teacher researcher made efforts on scaffold student learning by teaching them how to learn. The pattern of teacher researcher's teaching is outlined as follows: asking students to articulate what they learned from their reading, to explain the relevance of their reading to group project or the anchored issue, and to request a practical action plan for their proposed ideas or solutions. In addition, the teacher researcher facilitated discourse by presenting probing questions: clarification, explanation, challenging, and making meaningful connection.

Although the teacher researcher put efforts on facilitating discourse by using probing questions, students expected more direct instruction. Their learning motivation was declined because they were not goal-driven for their project. Neither did they obtain more comprehension about the issue of network-café, nor did they deepen their understanding of the subject matter of their study. They felt overwhelmed by their project because of lacking domain knowledge. They did not know how to delineate their project and find useful resources. They were also tired of discussing the same issue for the whole semester without any in-depth deliberation. They suggested that a variety of issues should be included in the course and believed they would have done better if more lectures were given in traditional face-to-face settings.

Students preferred face-to-face interaction rather than online interaction. They felt the sense of *reality* via face-to-face interaction. One student pointed out that none of them had experience on web-based learning and were not ready to be an active learner. They expected lectures and answers from the teacher. He suggested to devote a half of the class time to the lectures in the traditional classroom setting to serve as a transition. The majority of those who voted for face-to-face class meeting agreed with him.

The results also revealed that most of their group discussions were held in a face-to-face setting. Their participation in online asynchronous discussion was declining from the beginning to the end of the semester. Convenience was a factor. It was more convenient for them to discuss face-to-face because most of them took the same other courses. They met each other quite often. They further identified two major reasons for their avoiding online interaction: lack of keyboarding skills and the stability of the university network system. In fact, both students and the teacher researcher were overwhelmed by the technical problems of the web-based learning environment.

Most students were frustrated by insufficient computer skills that made their learning more time consuming. In fact, their learning time was doubled in comparison with those courses taught in the traditional setting. The time was spent in acquiring computer skills rather than learning domain knowledge. However, the intimacy of peer rapport was enhanced because they often worked out technical problems together.

Reflections

Balance between Structured Instruction and Empowerment Learning

PBL requires the balance between structuring learning and empowering individual in their learning. Deep learning does not occur with PBL if "doing" of a project takes precedent over "doing with understanding" because students do not have a driving question that fosters focused inquiry (Barron et al. 1998). Students' learning outcome of this study corresponded to the assertion by Barron et al. Students needed scaffold to transit from a teacher-centered approach to a learner-centered approach. Teachers should provide instructional scaffolding in encouraging goal-driven and meta-cognitive processing if project-based learning is considered (Barron et al. 1998; Laffey et al., 1998; Land & Greene, 2000).

Requirement of Domain Knowledge, System Knowledge, and Meta-cognition

Students participated in this study encountered serious difficulty of finding valuable information for their project because of lacking domain knowledge, system knowledge and meta-cognition. Traditional teacher-directed education creates a fundamental problem for project-based learning that emphasizes exploration and learner-centered thinking (Hill & Hannafin, 1997). Simply providing access to information does not guarantee effective learning (Land & Greene, 2000). Scaffolding students in fostering divergent thinking, multiple perspective building, critical thinking and problem solving is needed to help them adapt project-based learning. (Hill & Hannafin, 1997). The interplay between meta-cognition and domain knowledge are critical to the success in project-based learning.

Strategies for Leading to Active Learning and Reflection

Learning-community is critical to online learning (Palloff & Pratt, 2001; Poell et al., 1998; White &Weight, 2000). Interacting with instructors and their peers is essential if they are to master the concepts and skills associate with their profession (Ferry, Kiggins, Hoban, & Lockyer, 2000). The teacher researcher recognized the importance of online discourse and made efforts on facilitating discourse by probing questions. Unfortunately, the students did not have the sense of learning community and their participation was declined. According to Wang & Bonk (2001), online discussion is fostered by significant task structuring, controversial topics, student ownership, instructor modeling of system use, and role play. It also requires students to share thoughts, and analyze and critique others' thoughts (Wang & Bonk, 2001). Reflecting on the course design, the learning activities included the above elements by Wang & Bonk (2001). However, online discussion died for lack student active learning and effective self-reflection. Land & Greene (2000) assert that a learner-generated "need to know" is critical for purposeful knowledge-building. Students' active learning is critical to online learning (Harasim, Hiltz, Teles & Turoff, 1997; Palloff & Pratt, 2001; Simonson, Smaldino, Albright & Zvack, 2000). It is important to balance action and reflection, as well as facilitator intervention in project-based learning (Poell et al., 1998). The missing puzzle was what practical strategies would lead students to active learning and reflection.

Support of Learner-Centered Technology

Technology must provide scaffolds for a learner-centered approach requiring context-driven and individualized learning skills that not well cultivated in current educational system. Technological scaffolding for authentic inquiry must legitimately support and be aligned with both the teachers' interests in assessing student work, and the students' needs for support of the fluid and dynamic aspects of inquiry (Laffey et al., 1998). It is critical whether the assessment practices correspond to the goals and philosophies of project-based learning (Schwartz et al., 1999). Researchers have proposed models for technological support in project-based learning (e.g. Guzdial, 1998; Hill & Hannafin, 2001; Laffey et al., 1998; Schwartz et al., 1999).

Implementing PBL became cumbersome and impossible without the support of learning-centered technology. The web-based learning environment used for this study tended to be a teacher-centered design in comparison with the above models. The teacher researcher could not implement some online learning activities to get more student involvement (e.g. peer evaluation, sharing useful online resources etc.) because of the technology limitation. Consequently, a powerful learner-centered technology is a necessity to implement project-based learning on the Web.

Skills for Handling Emotional Issue

Establishing social organizations that promote participation is important to PBL (Barron et al., 1998). Palloff & Pratt (2001) emphasized the importance of creating a social context for participants to share their lives with each other to promote the intimate friendship in web-based learning. The "Café of Mood" was originally designed as a social organization by the teacher researcher. Unfortunately, the "Café of Mood" did not function as expected but became a discouragement to the teacher researcher because students posted their complaints on it. Some students indicated that they were too busy to participate in course discussion, but spent lots of time posting many complaints on the "Café of Mood." Such online student behaviors frustrated and disappointed the teacher researcher. The frustration, disappointment and discouragement impacted the student-teacher relationship negatively. This was an unexpected consequence.

A web-based PBL as a learner-centered approach is an educational paradigm shift for both the instructor and the students. The challenge for both teachers and students is to re-think their roles and responsibilities in the learning process (Anderson et al., 2001; Gersh, 2001; Hanna, Glowacki-Dudka, Conceição-Runlee, 2000; Kochtanek & Hein, 2000; Lawlor, 2000; Palloff & Pratt, 2001; Wang & Bonk, 2001). The change of teacher's role is both an emotional and a pedagogical challenge (Shrivastava, 1999). The paradigm shift arouses student resistance of change (Huba & Freed, 2000). Therefore, the teacher researcher needs skills to handle such emotional problems.

Conclusion

Teachers need help to be a coach and a facilitator. Students need support for taking self-directed projects, not just carrying out tasks assigned by the teacher. Both of them require new skills, approaches, resources and support systems while engaging in project-based inquiry (Laffey et al., 1998). Teachers require practical knowledge to balance empowering student learning on structured instruction. They also require practicable strategies that lead students to become active and self-reflection learners. They must scaffold students to acquire domain knowledge, system knowledge, and meta-cognition that are critical to the effective learning in web-based, project-based learning. A powerful learner-centered technology can support both teachers and students to effectively handle the challenge of the paradigm shift from teacher-centered to learner-centered. Finally, teachers should increase the level of tolerance to students' negative emotion and have skills for handling such emotional issues.

ABSTRACT

This paper details the design of an integrated system for Web-based distance education (ISWBDE. At the highest level, this system can be dissected into two sub-systems: an integrated course authoring system (ICAS) and an integrated course delivery system (ICDS). The integrated course authoring system (ICAS) is designed to help with, or automate the creation and management of curriculum, learning objects, and courses, whereas the integrated course delivery system (ICDS) is designed to generate personalized courses for individual students, to provide an integrated online learning environment on students' computers, an integrated tutoring environment for tutors and an integrated coordinating environment for course coordinators. The focus of this paper will be on the design of the whole system rather than the implementation, since we don't have enough space for those details.

1. INTRODUCTION

Distance education is an effective way "to remove barriers that traditionally restrict access to and success in university-level studies, and to increase equality of educational opportunity" (Athabasca University, 2002), and the World Wide Web is the most effective way to get people connected across almost any distance. Thus, Web-based distance education has become so far the best form of distance education, and is becoming a fast growing market worldwide.

As usual, Web-based distance education involves two phases: course development and course delivery. In the course development phase, an academic program including a detailed curriculum must be proposed, evaluated and fully developed according to the overall commitment and available resources of the institution as well as the current educational market. There are also other issues involved in program curriculum development and management such as credential and compatibility with programs offered in other institutions. Given a fully developed program, professors or subject matter experts can then plan, design and author each course in the program curriculum. The first thing in writing a particular course is obviously to define what a course is, or what should be included in a course package. This must be done at the beginning of a course development.

In the delivery phase of developed courses, it is generally required that instructors, tutors and students should work together in order to achieve certain designated teaching and learning goals. The detailed tasks for instructors, tutors and students to carry out in course delivery phase may be essentially different, however. So the first thing that must be done before a course can be offered or even developed is to decide what the instructor should do, what the tutors should do, and what the students should do, and most importantly, how.

In Web-based distance education neither of these two phases is an easy task. Therefore, it is important for institutions that offer web-based courses to provide course developers with some tools to automate the development of Web-based courses or as assistance, and to provide instructors, tutors and students some tools to accomplish their teaching and learning tasks over the World Wide Web.

In this paper we present the design of an integrated system for Web-based distance education that provides educators with support in both Web-based course development and delivery, and provides students with an integrated software environment to learn, to communicate with instructors, and to collaborate with others in both peer-to-peer and group mode. We will also recommend and describe certain important strategies and techniques necessary for the implementation. We will also explain the rational of each proposed functional module and recommended strategy and techniques for the implementation.

1.1 The integrated system as a whole

The whole integrated system we are developing is intended for upgrading or enhancing our existing course development and delivery system by providing instructors with an integrated system for course development and authoring, and providing instructors with an integrated teaching environment to teach, and providing students with an integrated system to accomplish their designated learning tasks, and to achieve the desired result. Accordingly, the whole system can be divided into two subsystems: an integrated course authoring system (ICAS), and an integrated course delivery system (ICDS). These two subsystems overlap at course server that takes input from the course authoring sub-system (ICAS), and makes output to the course delivery sub-system (ICDS).

In the following section we will describe details of these three parts of the integrated system for web-based distance education: the course authoring subsystem, the course delivery system and the course server that joins the above two subsystems together. We do not use the term e-learning here because we consider what we are doing now is closely relevant to the entire distance education system, of which learning is only a part.

2. The Design of Integrated Course Authoring System

In this section, we first detail the design of an integrated course authoring system, then outline some technical details on how the system should be implemented. The structure of the system is shown in Figure 1.

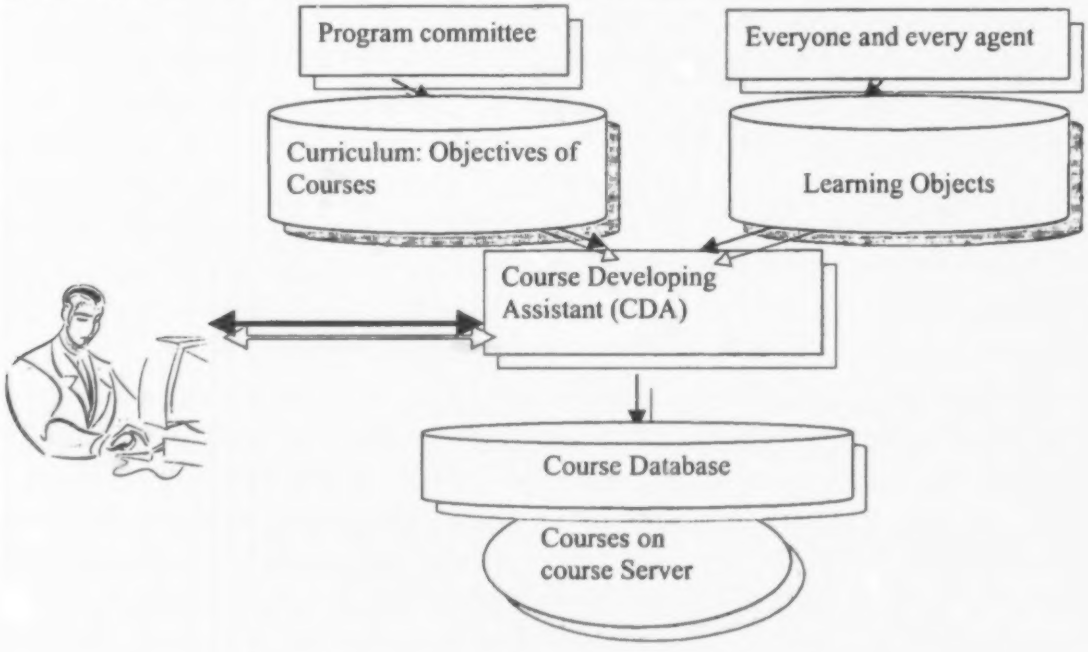

Figure 1: Structure of the integrated course authoring system

BEST COPY AVAILABLE

The ICAS system is based on two essential databases: a database of course or program objectives set up by the program committee and maintained by the program coordinator based on IEEE or ACM curriculum, a database of learning objects developed by a variety of people and software agents. A course is an association of course objectives with learning objects, and should be organised in accordance with certain widely agreed pedagogical approaches.

Therefore, the course developing assistant (CDA) should be design to help professors to: find out the right coverage of a course, create a list of units, then sections for each unit, and for each section generate a list of section objectives and then choose appropriate learning objects from the learning objects database. The CDA should also be able to automatically generate course study guide and all other files as well as data sets in the course database.

3. The Design of Integrated Course Delivery System

The integrated course delivery system consists of three parts for instructors/coordinators, tutors and students respectively. The relationships between these three systems are shown in Figure 2.

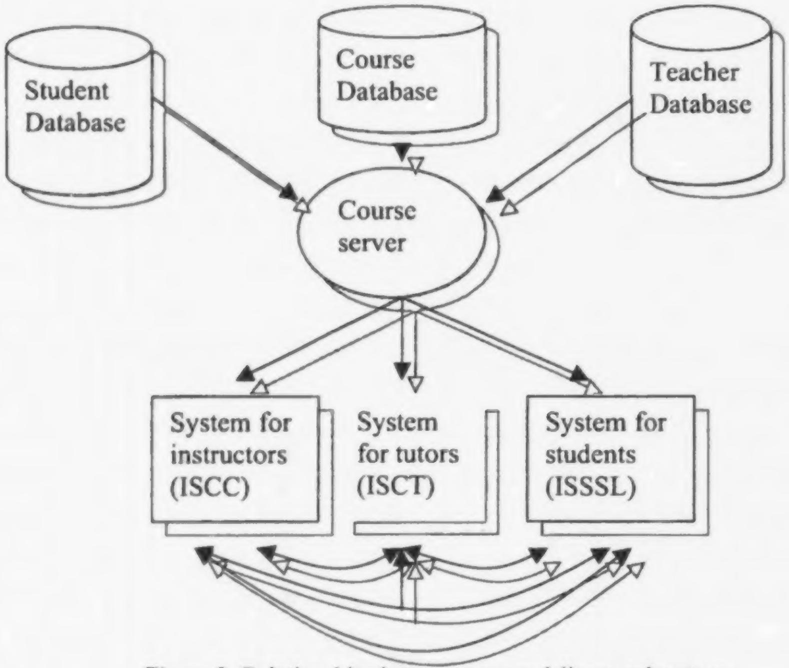

Figure 2: Relationships between course delivery subsystems

It should be noted that within our integrated course delivery system the three subsystems can interact with each other in both peer-to-peer and group fashion.

3.1 ISCC: INTEGRATED SYSTEM FOR COURSE COORDINATORS AND TUTORS

In Web-based distance education there is no face-to-face real-time instruction. As such, course coordinators often play roles of both coordinators and instructors in traditional universities. These roles include, but not limited to, *a.* assess students' qualification for course registration and make decisions accordingly; *b.* answer all hard questions and queries from students and even tutors; *c.* control the quality of teaching and learning by discovering and preventing plagiarisms, ensuring satisfactory performance of both tutors and students, continuously improving and quality and accuracy of course material including quizzes, assignments and exam questions.

To help course coordinators in accomplishing their jobs, our integrated system for course coordinators include the following modules:

1. ***Course presentation module***
   This module is essential to our integrated system. With this module not only course material marked in XML can be parsed and rendered with whatever output devices available on the user's computer. Learning objects including simulation and other course-specific programs can also be rendered in an effective way.

   In terms of network-related system performance and security, there is nothing to worry about, although some programs and simulation images will be of big size and can be more capable of doing things on client machines than traditional applets. The main reason is that most course materials such as course-related programs and images will be packed in the course package and downloaded by students only once, such as when a student has decided to start the course work. Later in the process of taking the course some updates or patches may be necessary for downloading from the course server, but that will not happen so often.

2. ***Course maintenance module***
   This module is responsible for assisting course coordinators to find inconsistency in course material, validate hyperlinks, identify and locate mistakes in the course material, and when capable automatically update course material based on coordinators' instruction and received messages.

3. ***Course messaging module***
   This module is similar to general email client such as Netscape messenger or Microsoft Outlook, but built into our integrated system for course coordinators (as we shall see shortly similar course messaging module is also built into integrated systems for tutors and students). The big advantage of developing and using such a built-in or specialized messaging module is that messages can be shared and manipulated by other modules easily. Also, some software agents can be easily built and deployed within such a specialized messaging module. Among these possible agents, an automatic question answering agent or FAQ agent will be most helpful since answering hard questions from students and tutors is an important duty of course coordinators.

4. ***Course conference module***
   While messages posted using the above messaging module are read and kept by the recipients and maybe the senders, messages posted at the course conference will be stored in a central server, and accessible to all course participants including coordinators, tutors and students. As usual, these messages will be threaded, and processed by some software agents for further actions such as course update, question answering. Although course conference is a place of open discussion about the course mainly for students, course coordinators do need to pay their attention to some hard questions. Technically speaking, the simple way to help course coordinators in this is to build a software agent into the conference module. What the agent is supposed to do is help identify those hard questions and send them to tutors or the course coordinator via the course messaging module, where some automatic question answering agents have already built.

5. ***Students assessment module***
   This module assesses both registered students and potential students who are seeking for professors' approval. The purposes of assessing a student registered in the course are: to identify potential plagiarism by checking the inconsistency among the results of quizzes, assignments and exams; to decide student's final grade; to evaluate the quality of the course by doing various statistics on student learning records. If the coordinator is also tutoring the course, assignment grading and management function should also be activated.

   To assess the qualification of a potential student, this module will simply communicate with the student seeking for missing information about his/her background knowledge and work experience, then compare with the course prerequisites. The assessment, and the data used in this assessment will be kept in a different database initially, but can be migrated to database for registered students.

6. ***Tutors assessment module***

As usual, a course coordinator is also the person, if not the only one, who is responsible for assessing and monitoring the performance of course tutors. The assessment is based on students' evaluation, statistics over messages in the course messaging and conference module.

7. *Task scheduling and monitoring module*

It can be easily imagine that course coordinators will have lots things to do. It is sometime very hard to decide when to do what without missing certain deadlines. The task scheduling and monitoring module is designed to identify questions to answer, emails to reply, and other tasks a course coordinator should complete and schedule these tasks for the coordinator, and monitor the progress of accomplishment.

The structure of ISCC including the relationships between the modules mentioned above is illustrated in Figure 3.

The integrated system is designed for use in a centre or department, and there is no such an integrated system at the university level yet. Therefore, until then messages from university registry and student administration regarding students, either in the course or merely interested in taking the course, will be sent to course coordinator at a regular email address, and be filtered and copied to a specific local file folder to which ISCC can access. These messages will then be processed by a parser for further decisions. Since students and tutors are all using their version of integrated systems, messages from tutors and students can be easily handled within the integrated course delivery system (ICDS).

Figure 3: Structure of integrated system for course coordinators

The integrated system for course tutor also includes a course presentation module, a course-messaging module, a course conference module, student assessment module and a task scheduling and monitoring module. The function and the design of the first three modules are similar to that of ISCC. The function of student assessment module for tutors, however, is different from the module for course coordinators. Course tutors are responsible for marking student assignments while the course coordinator is generally not unless s/he is also tutoring the course. Therefore, the course assessment module for tutors needs to be able to help tutors in managing and marking student assignments. These may include, for example, retrieving student assignments from somewhere, or accepting student submission of assignments, reminding tutors to mark assignments, and record the marks. The plagiarism detection facility can also be built into ISCT for tutors.

3.2 ISSSL: INTEGRATED SYSTEM TO SUPPORT STUDENT LEARNING

The ISSSL is designed to bear the following features to support students learning:

- Be able to present a variety of learning objects to student.
- Presented course material should be personalized
- Learning progress can be self monitored by a student.
- If needed, a virtual lab can be provided to students to accomplish their learning task.
- Allow a student to communicate with course coordinators, tutors and other students, and the communication can be traced and followed up.
- Allow both peer-to-peer and group collaboration, etc.

Based on modules we have discussed so far in the two previous subsections, some of these features can naturally provided within some of the modules it can share with ISCC and ISCT. These modules are: course presentation module, course messaging module and course conference module. While the courses presentation module will focus on XML for creating and processing specialized educational tag sets, it will also include players for 3D and multimedia presentations. Likewise the messaging module will give students the option of email, instant messaging, whiteboard, and chat). For students two new modules have to be provided within ISSSL: a module that can help students to schedule their learning tasks and monitor the learning progress and a module for identifying and selecting suitable peer collaborators. The design for integrated system to support student learning is shown in Figure 3 on the last page of the paper.

4. Discussions

We have presented in this paper the design of a specialized integrated system for Web-based distance education presents. Compared with systems based on general-purpose Web browsers, one of the advantages of a specialized system is that we shall be able to present all kinds of course material to students including programs for simulation and virtual lab and other sophisticate functions. One more function may be possible is to implement a online exam module within ISCC and ISSSL by utilizing video camera connected to student computers.

5. ACKNOWLEDGEMENT

This research is funded by DALE (Distributed Adaptive Learning Environment) project at Athabasca University.

The Study of Learning Progress for Distance Education Students in Taiwan

Sheng-mei (Jenny) Wang, Ph.D.
Assistant Professor, Department of Applied Foreign Languages
National Huwei Institute of Technology, Taiwan
wang170@yahoo.com

ABSTRACT: The purpose of this descriptive study was to identify factors related to dropout/retention for distance education students in order to identify variables which might promote participation through completion. The major focus of the study was to document the distance education students' learning progress and to identify variables that relate to their decisions for dropping out or staying in the program. The participants in the study were undergraduate students who originally enrolled in the distance education undergraduate program at the National Open University of Taiwan. The instrument used in this research was a mailed questionnaire for investigating the factors of dropout or retention for distance education students. The key factors which related to dropout or retention decisions for undergraduate distance education students found for this study are as follows. (1) demographic variables, (2) goal commitment, (3) social integration, and (4) academic integration.

Introduction

Over the past few decades, the number of programs and schools offering distance education as a cost-effective and as an educationally-efficient learning system in higher education has increased rapidly in many developed and developing economies. The need to keep up with technological advances, job training or retraining, and below par literacy skills are among the many reasons that adults need more education and return to school. Mature adults need an educational system that has the flexibility and diversity to provide advanced education for everyone (Huang, 1997). Fortunately, distance education is the most obvious and efficient solution. Distance education reaches across geographic boundaries and provides opportunities for higher education and technician level training to those unable pursue traditional programs (Sherritt, 1996). It provides flexible access for the traditional student and an educational "second chance" for adults who were previously denied opportunities (Rumble, 1986; Van Enckevort, 1986; Garland, 1992).

However, many of the recent distance education studies do not adequately address the learning experience of distance education students in a higher education while they have focused on student outcomes, such as academic achievement and intention to enroll in other distance education courses. Glatter and Wedell (1971) state that the dropout rate in distance education classes is much higher than would be expected in full-time courses and could reach 70 percent. According to Kember (1995), Rumble (1982), Wichit Srisa-An (1984), and Fleming (1982), the dropout rates in some distance education schools are higher than expected. In the distance education university in Venezuela, the dropout rate was 79%; at the Open University of Thailand, 62% of the students were no longer enrolled after two years; in Pakistan's distance teaching university, the dropout rate was 99.5%

as early as the first semester. These examples show that distance education institutions generally lose half or more of their enrolling students.

This lack of retention is also the situation at the National Open University (NOU) of Taiwan. It is recorded that only about 5% of the students who completed the registering process at the NOU obtained a degree. Therefore, this study aims to identify the significant characteristics of distance education students who have dropped-out or continuously and successfully progressed in the distance education program at the NOU of Taiwan. The major focus of this study was to identify the factors which might relate to the students' decisions for dropping out or staying in the distance education program, and to gain a better understanding of students' perceptions of their current academic setting.

Statement of the Problem

The problems can be summarized into three central questions. First, who is the distance education student? How do students' characteristics relate to their decisions of dropout or retention? Second, what are students' reasons for dropout or retention in the program? How do the variables in terms of *external attribution, emotional encouragement, and motivation* relate to the students' decisions of dropout or retention? Third, what are the students' perceptions of their academic setting in terms of interaction with the instructors/institution and the imp ression of their current program? How do these perceptions relate to their decisions of dropout or retention?

Literature Review

Studies (Drummond, 1989; MacKinnon-Slaney, 1994; Sheath, 1965; Tinto, 1975; Bean & Metzner, 1985, 1987; Kember, et al., 1992 & 1994) have indicated that the factors of support and encouragement (such as family support and encouragement), external attribution (such as insufficient time, financial difficulties), and motivation (Entwistle & Ramsden, 1983; Wlodkowski, 1985a & 1985b; Knowles, 1984; Maslow, 1970; Kember, et al., 1992 & 1994) were related to the student's learning experience.

Many of the factors of dropout and retention research in distance education include demographic characteristics of the individual learner over which the educational institution has little or no control. However, for the institution, it is significant to consider these individual characteristics. Several studies (Fjortoft, 1996) identify the reasons which lie behind student dropout as an important task in order to provide trends to an institution. In fact, student dropout is usually costly to the institution and the individual (Metzner & Bean, 1987). Furthermore, a high dropout rate also suggests a failure to solve a larger social issue, the equality of educational provision (Belawati, 1998).

An interactive process between the individual and the institution may also relate to students' dropout rate in higher education (Tinto, 1973; Bean, 1985; Metzner & Bean, 1987). Cable television is currently being used as the delivery media at the NOU. Researchers Ritchie and Newby (1989) found that in a television classroom environment, students experienced less involvement, less ability to ask questions, and less overall enjoyment in the learning experience than did students in a traditional classroom setting.

Methodology

Research Design

A descriptive survey method was used to collect data. The study used a mailed questionnaire to gather data from distance education students at the NOU of Taiwan related to their enrollment decisions of dropout or retention. The questionnaire was designed to answer the research questions and consisted of closed-ended questions.

Subject Selection

From the target/accessible population (N = 10,133) who first entered as full-time freshman four years ago at all of the distance education centers in mainland Taiwan , a proportional stratified random sample of the NOU distance education students from eleven distance learning centers was selected to arrive a representative sample size at a total sample (n) of 375, as recommend by Krejcie and Morgan (1970).

Return Rate

The overall response rate for this study was 81.07% after 3 follow-up mailings followed by the initial mailing.

Findings

Research Question #1

The responses to the first research question, "How do the selected demographic characteristics relate to students' decisions of dropout or retention?" were analyzed using the point-biserial correlation coefficient or phi coefficient (ø)/Cramer's V statistic based upon the type of variables to be correlated.

The results of the point-biserial correlation coefficient indicated that there were statistically significant relationships with the enrollment status for the categories of number of semesters, grade performance, age, and salary. The results of phi coefficient (ø)/Cramer's V statistic indicated that there were significant relationships with enrollment status based on gender, sponsorship, occupation, and education.

Research Question #2

The responses to the second research question, "How do the factors of External Attribution (Insufficient Time, Events Hinder Study, Distractions, and Potential Dropout) relate to the students' decisions of dropout or retention?" were analyzed using the point-biserial correlation coefficient. The results indicated that a significant relationship existed between the enrollment status and *External Attribution* (r= -.257, p= .000), which included subscales of *Events Hinder Study* (r=-.346, p=.000), *Potential Dropout* (-.215, p=.000), and *Insufficient Time* (-.140, p=.000) at the .01 level. The external attribution means negative social integration and is sub-divided into four subscales in the instrument.

Research Question #3

The responses to the third research question, "How do the factors of Emotional Encouragement (Enrollment Encouragement, Study Encouragement, and Family Support) relate to the students' decisions of dropout or retention decisions?" were analyzed using the point-biserial correlation coefficient. The results of the point-biserial correlation coefficient indicated that no significant relationship existed between the factors of Emotional Encouragement (Enrollment Encouragement, Study Encouragement, and Family Support) and the students' decisions of dropout or retention.

Research Question #4

The responses to the fourth research question, "How do extrinsic and intrinsic motivation factors relate to students' dropout or retention decisions?" were analyzed using the point-biserial correlation coefficient. The results of the point-biserial correlation coefficient indicated that no significant relationships existed between extrinsic motivation and students' enrollment status as dropout or retention decisions. However, there was a significant relationship between students' enrollment status and intrinsic motivation (r=.186, p=.001) at the .01 level. It indicated that as participants had more intrinsic motivation, they were more likely to stay enrolled or complete the program compared to those with less intrinsic motivation. However, it was only a low relationship between intrinsic motivation and enrollment decisions of dropout or retention.

Research Question #5

The responses to the fifth research question, "What are the students' perceptions of their interaction with the instructor/institution and their perceptions of their current program? How do these perceptions relate to their dropout or retention decisions?" were analyzed using the point-biserial correlation coefficient. The results of the point-biserial correlation coefficient indicated there was a significant correlation with enrollment status based on Negative Impression of the Program (r= -.183, p= .000) and Positive Interaction(r= .207, p=.000) at the .01 level. The results indicated that participants who expressed more dissatisfaction with the program and its support tended to dropout from the program more frequently than those who expressed less dissatisfaction with the program. In addition, the results also indicated that the participants who gave more positive feedback tended to stay enrolled or complete the program more frequently than those who did not give positive feedback. The positive feedback referred to course materials, tutoring, assignment marking and administration.

Conclusions, and Recommendations

Conclusions

Based on the results of the present study, the researcher identified the key factors related to dropout or retention decisions for undergraduate distance education students:

1. Demographic Variables: age, number of semesters, grade performance, salary, gender, occupation, education, sponsorship.
2. Goal Commitment: intrinsic motivation
3. Social Integration: insufficient time, events hinder study, potential dropout
4. Academic Integration/incompatibility: positive interaction with instructors/institution, negative impression of the program

Theses four factors are related to dropout or retention decisions for the undergraduate distance education students. Among these factors, the students' grades and academic integration are more under the control and can be managed to some extent by an institution.

Recommendations

Based on the findings of this study, the researcher makes the following recommendations that might be taken by the institution to improve the distance learning environment. Finally, recommendations for future research in the area of distance education are addressed.

Recommendations for institutions:

1. The institution should offer flexibility within units and wide choice of units to form a course in order to maximize intrinsic motivation students.
2. As suggested by Landtroop (1998), students' grades can be influenced by each professor's teaching/learning philosophy and the instructor/student interaction. Therefore, the institution should create some constructive ways to involve the students in learning and encourage instructors to interact with the students.
3. Every distance learning center should have enough staffs to assist students. The employment of counselors is also recommended. Counselors should be able to assist students in integrating study demands with work, family, and social obligations.

Recommendations for future research:

1. Conduct qualitative studies to confirm and clarify findings.
    a. Interview individuals from the various distance learning centers.
    b. Interview students who have decided to no longer enroll in the program in order to glean information about possible factors associated with student dropout.
    c. Interview students who have completed the program or stay enrolled in order to obtain information about possible factors associated with student retention.
    d. Interview faculty who have experience with teaching and interacting with distance education students.
2. Investigate the current policies and practice of the National Open University that impact student's learning.
3. Research must continually explore the relationship and factors associated with dropout or retention. Establishing a longitudinal study and monitoring students' learning progress over time is suggested. The factors related to stop-out should also be studied. What were the factors leading to their dropout? What intervention could be provided?
4. The timing of dropout requires more investigation in distance education. For example, factors contributing to early dropout (dropout soon after enrolling) versus later dropout should be explored. What were the factors leading to dropout?

Abstract *In educational environment, it is desirable to support the mechanism by which persons can participate in their interesting communities without any troubles and also promote their learning activities increasingly or successfully. In particular, now that web-based educational environments have been successively organized under a virtualized communication network or a logical interaction space the architectural framework must be investigated. In this paper, we address an architectural framework of handling knowledge in the education from a viewpoint of personal activity. Our objective is to design the support environment of personal activity in the education, based on the seamless transition mechanism among individual educational environments. In order to make the viewpoint of our investigation clear we introduce a three-layers model for educational support architecture. Three layers are educational environment, support system and person role, from the top layer to the bottom layer. The lower layer is organized so as to contain the functional features in the upper layer, as basic and composite facilities for the construction.*

Introduction

The computer systems coupled with information networks take important roles to establish the infrastructure for information society from a logical point of view, in comparison with the infrastructure for our social life-lines to be supported traditionally by architecture or civil engineering. So, the knowledge infrastructure environment grows up without any doubt as our information-oriented society to be desirably expanded in the 21st century. Our daily activities are more or less dependent on the utilization/adaptation of our heuristically-experienced or traditionally-accumulated knowledge, and the effectually computer-supported mechanisms must be investigated to establish such knowledge infrastructure environments[1].

The computer support for educational activity is one of important subjects, and until today various research subjects have been investigated eagerly and progressively. Many of these traditionally investigated subjects unfortunately were disjoint from other research viewpoints with a view to establishing globally or cooperatively integrated educational environment. This historical trend may be dependent on the large desirability and dream of educational application for computer power. The discussions or considerations of educational activity or knowledge growing process should be sufficiently exchanged or attacked. Concerning with knowledge growing process, I.Nonaka, et al. proposed an aggregated model (e.g. SECI model) for knowledge management[2,3]. Although SECI model is not always appropriate to investigate educational activities of persons, at least the framework is very interesting in our discussion. Also, we have already discussed an architecture for handling knowledge in education with a view to designing uniformly integrated educational support system[4-6]. However, our conventional research project did not focus on the educational support framework for personal activity because our research view was dependent on the educational support mechanism in the organization, like SECI model.

In this paper, we discuss the constructive framework of handling knowledge in the education from a viewpoint of personal activity, but not with respect to complementary trainings or exercises in the organization. Our objective is to design the support environment of personal activity in the education, based on the seamless transition mechanism among individual educational environments. In order to make this modeling viewpoint clear, we introduce three-layers model for educational support architecture. Three-layers model arranges analytically our knowledge activity with respect to three measurements: educational environment, support system and person role. We address our modeling mechanism

BEST COPY AVAILABLE

successfully, based on the correspondence between upper and lower layers with a view to making it explicit that educational activities defined in the environment should be interpretatively implemented as the behaviors of individual persons.

Framework

The effective environment of knowledge management in the education must support various behaviors of individuals smartly without any operational differences because the personal activities are too strongly dependent on the personality and progressiveness of individuals but are not uniformly controlled under the organization. Of course, it is very difficult to attain this requirement sufficiently since ordinarily we are not always assisted well to our educational activities by man-to-man or by one-to-one relationship, but in many cases act in ourselves or are supported together by one-to-many relationship. Our educational support architecture is illustrated conceptually in Figure 1. This architecture is composed of three layers: educational environment, support system and person role. In three layers, different modeling views are correspondingly mapped from the upper layer to the lower layer so that the modeling characteristics in the upper layer should be constructed interpretatively by the corresponding characteristics in the lower layer.

The educational environment points out distinguishable categories in our educational activities: private learning, group learning, group lecture and private lesson. These distinguishable categories are observed from our practically experienced education systems: the private learning is corresponding to our self-learning such as pre-learning and post-learning for school lectures; the group learning does to the discussions, meetings, exercises, etc.; the group lecture does to school lecture, public seminar, etc.; and the private lesson does to man-to-man lesson, private coaching, etc. Of course, these categorized activities are functionally established by means of any educational support systems such as CAL (Computer Assisted Learning) for private learning, CSCL (Computer Supported Collaborative Learning) for group learning, CAI (Computer Assisted Instruction) for group lecture and ITS (Intelligent Tutoring System) for private lesson. These educational support systems have been developed with a view to being apt respectively to individual education systems, which are currently organized as social structures/mechanisms. Of course, these support systems must be applicable to various types of users, who take roles to keep effectually instructional and conversational interactions. The person role makes the interactive- or functional-tasks of persons, who take plays actively or passively according to their situations and objectives in individual educational environments, explicit.

The functionality in the educational environment is interpretatively mapped into educational behaviors of persons and the educational environment is explicitly defined as the practical paradigm. The person roles can be looked upon as the features of users in the educational support systems, and student, teacher, tutor, coordinator, speaker, etc. are effectual roles. The educational environment in the top layer is individually categorized by characteristics of educational support systems and the categorized educational support systems are characterized by the roles of participated persons as actors. So, it is important for the educational environment to organize seamless activity fields in accordance with person roles and also construct the functionality of making seamless activities possible among person roles. Of course, the person role is variant for individuals: the same person may take different roles in accordance with the objectives/motivations for the educational activities.

Support View for Educational Activity

In the educational environment, the educational styles which we can distinguish in the real world are categorized into the private learning, group learning, group lecture and private lesson. These educational styles are distinguished in accordance with two factors: the number of students and the number of teachers. The number of students is 1 or n ($n>=2$), and the number of teachers is 0 or 1, respectively. Figure 2 locates such educational styles into two-dimensional space with respect to these two factors. Of course, we often observe the educational activity in which the teacher is a basic composite actor even on the group learning: in particular, in the large-scale group discussion which has not been associated with leaders, the teacher takes an important role as an advisor or a coordinator. Figure 2 does not define the categorization for our educational activities of persons, but arranges the constructive relationship among different educational styles.

As for these educational styles, today the typical educational support systems, which are currently usable or proposed, are classified into four types of system configurations such as CAL, CSCL, CAI and ITS. These support systems are correspondingly consistent to four styles of educational activities. Figure 3 shows such a corresponding relationship between educational styles and educational support systems. In Figure 3, it is strongly drawn that CSCL and ITS related respectively to the group learning and private lesson are not strictly constrained by two factors: number of students and number of teachers. CSCL and ITS are depicted so as to be expanded to the partitioned domain "group lecture" (which is defined by many students and a teacher), assigned to CAI. In CSCL, the presentation process in the symposium or congress is similar to that in the group lecture in many cases. Similarly, ITS is extensible to the domain of CAI in case that one tutor teaches or discusses a few students together at once or one by one. At least, students are timely located to one of four types of educational support systems, according to their educational activities and pre-assigned schedules of learning. Thus, it is important that the seamless transition mechanism among different educational support systems should be implemented. Of course, these educational support systems are not adaptable to only students, but also must be applicable to persons such as teachers, advisers, instructors, etc., related closely to students. Table 1 arranges person roles for this discussion about extended support activities. Figure 3 shows the improved interaction among individuals in each educational style: in comparison with Figure 2, the interactive relationships among composite elements are complex in CSCL and ITS. Namely, this improvement insists that individual educational support systems should provide adaptable facilities to different classes of persons in accordance with person roles, which have to be done in the educational activities.

Seamless Activities among Educational Styles

Figure 4 illustrates different classes of persons in each educational support system. Here, we must pay an attention that the person role in each educational support system is pre-assigned when the transitive movement from the private learning to another is occurred: for example, a person takes a role of university student in one case, and in another case he takes a play of tutor for students in an elementary school. Additionally, all educational activities are started on the private learning as the origin. This is because the private learning is looked upon as the pre-education for various educational activities. In Figure 4, persons who participate in the group learning are categorized into three types according to the size or scale of meeting: small-size, large-size and symposium-like meetings. Also, in such meeting categories persons are classified into students, coordinators and speakers. Namely, three kinds of meetings are distinguished by the construct among these composite actors: the small-size meeting is organized only by students; the large-size meeting is controlled by the coordinator so as to carry on the discussion in the well direction or promote active information exchanges; and in the symposium-like meeting speakers (or presenters) newly participate with the help of coordinator.

Figure 4 shows the transitional relationship among different educational activities attended with person roles. Ideally, it is hopeful that the environment should support various styles of educational activities by the cooperative mechanism among different functions. The educational environment which can support the seamless sequence among various actions and reactions powerfully is better. We investigate the seamless activities in Figure 4 with respect to person roles. Figure 5 shows various types of transitive processes among different support systems. The private learning is interpretatively looked upon as the pre-stage for another educational activity, and when one objective or successive behavior of personal plan is scheduled, a sequence of actions must be determined with person role, which was assigned in the private learning. In various educational styles, persons prepare their learning subjects to participate in pre-assigned meetings/parties. The person roles for participation are very changeable in accordance with occasional motivations. In this case, the private learning is a very simple and fundamental stage, and also is regarded as the pre-learning and post-learning phases for another educational style. Thus, the educational support system must always work cooperatively with each other so as to integrate various facilities and share data storage (or knowledge resources) accumulated by individual activities.

Conclusion

In this paper, we addressed an architectural framework for educational activities of persons. In particular, we proposed three-layers model, which is composed of educational environment, support system and person role. Our idea is to integrate them adjustably under the corresponding relationships among layers, and transform interpretatively the concepts in the upper layer to those in the lower layer. Concerning with this approach, our objective is to investigate knowledge handling mechanism from a viewpoint of person activity. The effectual results discussed in this paper are as follows:

1)framework of seamless personal activities among educational environments;
2)framework to be supported practically by computers.

Of course, currently these frameworks are not always sufficiently investigated: in particular, the integration of individual frameworks should be addressed strongly. Also, we should establish the educational knowledge handling paradigm and implement effectual educational support environment and functionality-oriented mechanism on our Internet world[7].

As our next step for managing personal knowledge activity, we should investigate the total architectural framework which makes the interactive structure among various types of knowledge operations clear[8].

Acknowledgement

We would like to thank our research members in the Lab. for their eager discussion and cooperation.

Transcultural learning in Internet-based learning environments – European methods and experiences

Peter J. Weber
University of Hamburg (Germany)
Institute for International and Comparative Education
weber@erzwiss.uni-hamburg.de

Abstract: This paper deals with a survey on three case studies of various arrangements for intercultural learning via the Internet in Europe. On the one hand the empirical research is based on theoretical reflections about intercultural competence needed in a multicultural society on the other hand it is grounded in the pedagogical discussion of media competence. The main goal of the research is to determine the sustainability of Internet-based learning arrangements and a virtual mobility for campus based students.

1. Introduction

With the technical development of the World Wide Web in the early 1990's, the Internet was theoretically accessible for everyone, at least in the industrial nations. Without a doubt, the traditional electronic media could never have triggered such a development as has the fusion of computer, telecommunication and electronic media (Willke 1997). This can be largely traced back to the optimization and redesigning of communication processes which present a possibility for businesses to respond to the higher demands regarding costs, quality and flexibility in the international marketplace. According to OECD estimates, 30% of the volume in the areas of communication, finance and smaller trade and 20% in education, public health and government will be influenced by the electronic trade (OECD 1999, 9).

A general increase of Internet users can be counted on worldwide. Virtual contact situations will be thus influenced especially by the giants of intercultural and media competence. An intercultural competence in virtual contact situations can contribute to both a globalized and regionalized society, permitting peaceful co-existence since they lead to a large degree to the dismantling of prejudices and stereotypes. Yet the interaction between intercultural and media key competencies is rarely considered, let alone the subject of social competence, which can be regarded as decisive in global as well as regional contact situations in the Internet. This contribution will deal next with the relationship between intercultural competence and internet based virtual mobility situations, in order to enrich consciously the very technically oriented discussion with one further aspect. Based on the mutual influence between Internet and intercultural competence, the influence of a social competence through virtual mobility will be discussed through the demonstration of three case studies. Due to the paradigmatic character of the chosen case studies, this can be of definite importance for the development of a 'global social competence' via virtual mobility.

2. Transcultural competence and virtual mobility

Just how far the Internet poses a chance for intercultural learning depends very much on how far the Net lends itself to learning processes. The question is which new opportunities the Internet-based learning environments for virtual mobility offer for the development of intercultural competence for learners of different anthropological backgrounds. With that, two central problems are raised:

- How should the target size of a transcultural competence be designed in relationship to the development of a virtual world?
- Which Internet learning environments should be chosen from the existing multitude in order to arrive at lasting design criterion?

One possible target size lies in the connection of the effects of the new media with a differentiated understanding of society. Today, a meeting of cultures is let loose from a central nation state through the new media. This is due to the continually progressive supplementation of the national electronic and printed media through new international media, which obey other principles altogether (Schröder/Zimmer 1995). If media in the nation states is on the whole only planned for its lnguistic region, global media of international communities orientates itself toward its multilingual users[1]. At the same time, technical development makes the integration and interactive design of various media possible. At this point the process of community creation becomes increasingly important since social actors can join forces with one another or with many others out of common interest. This process will be made easier in the international context through the Internet. And with it, a substantial importance of the new media could be in making possible the formation of transnational societies which themselves consist of many sub-societies. The new media therefore has the ultimate effect of being identity-founding. These transnational societies unite people of different cultures; for example, through trade, immigration and emigration or through common activities in the Internet by virtual mobility. This doesn't mean that the state and the related concept of the international society become obsolete or that the artificial particalization of the society must increase (Kleger 1997). This transnational space is at the same time transcultural, requiring a corresponding competence from the social actors which can no longer be fixed to an intercultural understanding. It must concern itself with a transcultural competence which allows the social actors to deal with many cultures of the transnational society, since with the multitude of contact possibilities, not all specific cultural competencies can be conveyed. Objectives for a virtual mobility can therefore be culture-overlapping fundamental competences, to which a transcultural social competence belongs, consisting of sociability, communicative flexibility and sensitivity.
To the solution of the second initial problem – which Internet learning environments should be drawn upon for the analysis of intercultural learning via virtual mobilty in the Net – a categorization lends itself which has been obtained from the analysis of world-wide collaborative learning environments for presence universities. It is concerned with learning environments which work by sensitization through explanation and training (Type 1), through consensus creation (Type 2) and through knowledge construction (Type 3) (see Ribold/Weber, 1998). For Type 1, case study CCED (Cross Cultural Explorations and Dialogue) has been chosen, whereby it should be mentioned that since winter 1998, this training with online-communication has been expanded with accompanying video conferencing. At the time of the interviews, this feature hadn't yet been predicted. DEMETER (Distance Education Methods in Teacher Education and research) was chosen for Type 2 and HALÜBO (Hamburg/Lüneburg/Bochum) for Type3.
(There will be a hands-on demonstration of the three leraning environments during the presentation.)

3. Analysis

The data collection in winter 1997/98 for the three case studies works with a combination of qualitative and quantitative methods. In order to receive specific information about the environments within a university system, the data, which is analyzed here, has been taken from the data pool of the German universities about the three projects. There were three collection methods in total. A questionnaire was distributed before and after the courses so that distinctive personality characteristics of the learners of the environments could be identified. A qualitative analysis of the communication environments, such as message boards, ensued from a look at the intercultural or rather, transcultural learning process which included the comparison of the categorization according to the Software Typology of Baumgartner and Payr (1994). With regard to the enduring effects of the study results, interviews with experts were conducted in connection with a workshop.

The main objectives of the study are as follows: the study should indicate effects of the technical and pedagogic variations of Internet learning environments. It should also indicate the typical changes in distinctive personality characteristics in regard to the target size of a transcultural competence. The study should finally determine general construction criterion of Internet learning environments with regard to pedagogic constructivism.

---

[1] In this contribution, we will address the tendency toward globalization through the Internet only, not that of regionalization, which exists as well. The analysis of the language usage of websites indicates that the 'globalization language' English does not play the dominant role as was supposed. Websites are mostly bilingual, in a national language plus English: this points out the further creation of regional and local virtual space, in which the intercultural and media competences remain indeed as equally important as in the global space (Databank Consulting 1997).

4. Results [2]

The results of the exploratory study conducted before the start and at the end of the courses (with 173 students who had rather weak international and technical knowledge beforehand) can be divided into three areas: efficacy of the learning environment on the learner, typical distinctive personality characteristics and their changes after the courses and finally, the potential for innovation of the Internet learning environments of these three types. In the following, the results regarding the distinctive personality characteristics will be introduced by way of examples. These characteristics constitute the core of the study since it is through them that the question of which learning environment best supports the development of transcultural competence will be investigated. Transcultural competence was set within a sub-construction of the question which consists of 16 dimensions and 41 variables. The variables were adapted from the personality research for transcultural inquiry. The analysis pursued Latent class analyses (LCA), in order to procure typical answer patterns (Rost, 1990, 1996).

Figure 1 shows an example of 4 typical answer patterns in the dimension sociability, as appearing before and after the Internet courses. The largest group before the course is the "hesitant" type who, although having only minor anxiety towards other cultures, is quite hesitant in establishing and maintaining contact themselves. Less hesitant is the second type before the course (the "sociable" type), who also demonstrates strengths in establishing contact. The evidence for mistrust towards people from other cultures is rather ambivalent, existing only at the beginning. The "sociable" type reappears again after the course and in this case, comprised over 60% of the students. A learning effect had taken place as the sociable group is by far the biggest; even when the individual LCA types don't have to be composed of the same people.

The hesitant type no longer appears after the courses; rather a more active type with noticeably little anxiety regarding foreign cultures. A general finding is that the Internet courses led to increased sociability for most participants. This result is repeated for nearly all 16 dimensions of the measured distinctive personality characteristics. After the courses there was a general gravitation by all the types toward the categories of transcultural competences and at the same time towards a higher positive response niveau. One can therefore assume an overall positive influence of the Internet learning environments on transcultural learning success.

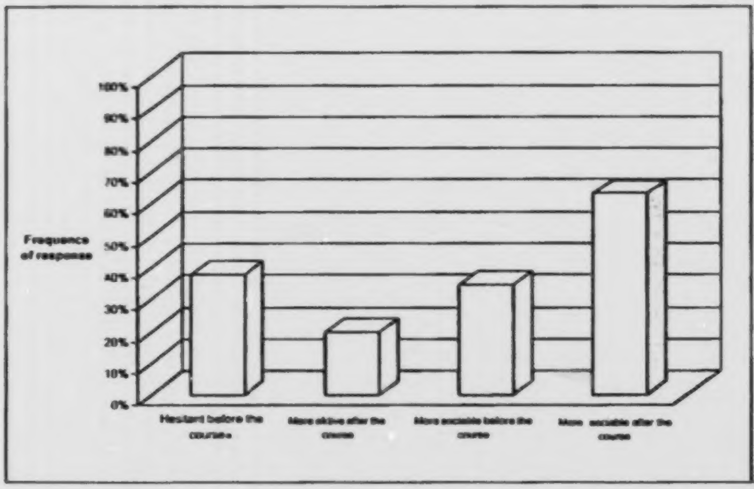

Figure 1: Sociability dimension

The point of departure for a look at the changes in the differentiations after the three Internet courses is the classes or types of the LCA analysis, as described above. According to these types and with the help of cross-tabulation, it will be investigated in which typical response pattern differenentiations occur after the course. Within the first dimension, hardly any differentiations in the strengths can be found in the discrete examinations of the courses for the categorization of the types 'Hesitant' and 'Sociable'. All three courses in this dimension more or less reach the objective of increasing sociability in the participants after the course. This can be explained by the design of the courses, in which all three included a phase of direct contact with the help of the medium of Internet (e-mail, chat, etc.). Two special features result through the technical construction stipulations of the Internet. Firstly, independent of the pedagogic design, it is apparent that the participants are more sociable in intercultural situations through the inclusion of electronic communication possibilities which they themselves specify. Secondly, it became obvious that limits to the technical implementation of problem oriented environments exist due to their enhanced complexity which can lead to undesirable learning results despite the allowance for communicative target categories.

5. Discussion

On the whole, all three learning environment types studied proved capable of initiating a learning process centered especially in the area of social competence, going beyond culture toward a sociable, open and considerate learner. Within the framework of the exploratory character of the study, it can be suggested that the Internet is well suited to the construction of transnational societies since, through the development of social competence, the process of community creation will be supported. People of very different nations and cultures band together out of common interest. This bond can also be understood in terms of the perceptions of one's own subjectivity which are part of identity and culture developmental processes. In this way, culture can be understood as a complex bundle of subjectivities (experiences, values, norms, ideas, attitudes, dialects, etc.) and objectivities (activities, behavior, language, artifacts) which assist everyday orienteering and life mastery (Roth 1996, 260). With regard to Max Weber (1972), community creation can now be seen as the more subjective process, whereby individuals come to a group formation out of subjective reasons, in contrast to society creation in which the rather objective motivations play a role. For the future multicultural community, it is exactly the process of community creation which may possess the greatest creative potential. And with it one great importance of the new media for the world society could be that the new media actually has the effect of being identity-founding in a world of international and multicultural communities where it is possible to form international communities of various actors (organizations, individuals, businesses, etc.) consisting of many sub-communities. All these communities will cohere out of common interests and, from the start, need in no way, for example, follow the majority of any nation state.

It is also to be borne in mind that the best learning effect could be a result of a combination of the three types since a comprehensive transcultural competence cannot be provided by just one type of the Internet learning environments. This would be conceivable in serial modularity, although it would be problematic in the European university system which is neither institutionally nor organizationally very flexible. The teletutoring structure should therefore greatly influence the virtual and partially virtual universities of the future (Geyken/Mandl/Reiter 1998). At the same time, only few universities are likely to prevail as truly virtual institutions (single model) such as the University of Phoenix. They are rather likely to become more Add-on or More-Quality models (dual mode), which perform parts of their services virtually (Krempel, 1997).

6. Conclusion

In the future there will surely be more people who will have tertiary educational experience in a virtual space, even without being explicitly prepared for it by an educational institution. Therefore the existing concepts of multicultural education must automatically be questioned as to whether their concepts are adequate enough to prepare people for increasingly enmeshed cultures within corresponding learning processes. This doesn't mean that the area of tertiary experiences should obscure the other experience areas, but it should be prognostically assumed that it will play a larger role in hypermodern societies than in postmodern ones (Telepolis 1997).

Of much greater importance is that the ephemeral life-models of postmodernity - just as in hypermodernity – will retain their validity. It will be impossible for the individual to be prepared for the life-long challenges in the rapidly changing social roles, structures and duties. The decisive factor should be world-wide technical and trans-cultural competence since they make the individual citizen flexible in the specific creation of private and professional life-plans. As they are primarily coupled with the new media, they should also be striven for within its frameworks. The results of the studies, introduced here by way of example, advocate that virtual international Internet learning environments lead to a change in the learner's social competence with a view to a global social competence and virtual mobility Hence, it is to be in future even more intensively investigated how multicultural education concepts concerning the new media can be complemented.

Presenting Complex e-Learning Content on the Web: A Didactical Reference Model

Franz Weitl, Christian Süß, Rudolf Kammerl, Burkhard Freitag
University of Passau
{weitl,suess,freitag}@fmi.uni-passau.de, kammer01@fsuni.rz.uni-passau.de}

Abstract: Education can profit significantly from hypermedia und e-technologies. However, in our experience the majority of students having the choice of learning on the computer or from a printed script or book prefer the latter when it comes to "challenging" formal domains. For online learning material to be successful its structure and presentation have to reflect the characteristics of hypermedia and the web. This paper presents a *model* of the *didactical structure* of online learning content based on methods of instructional design. The model specifically addresses two major problems of the medium web for learning: *loss of overview* due to low information density of the medium and *short attention spans* due to fast fatigue of perception. The model serves as a framework which guides the author in structuring even abstract and complex content such that it can be efficiently learned on the web. The model is the basis of how 12 German universities structure their content in the joint project WWR (Wissenswerkstatt Rechensysteme – Knowledge Factory for Computing Systems) which aims at providing a pool of 150 XML-based online learning modules in technical computer science.

1. Introduction

In our experience from current e-learning projects [NE02, LA02, WWR02] e-learning needs to take different learning styles into account to be successful. Thus in all of these projects we decided to publish the course material in at least two formats: (1) as a web- based e-learning course, (2) as a traditional printed script. However, internal evaluations have shown that the majority of students prefer the print medium, when it comes to "challenging" complex or abstract subjects which are typically taught in higher maths and computer science education.

This observation is not just coincidental. We identified two major disadvantages of the medium web for learning formal material:

- Relatively low information density: the amount of information which can be presented on the screen is limited as compared to print media. This leads to a quick **loss of overview**, when the presented material is complex.
- Non-optimal learning environment: research results show, that the perception tires out quickly when the recipient has to grasp a large amount of new information on the screen [KS89]. As a result, authors of online material have to cope with particularly **short attention spans**.

To tackle these problems we developed a didactically motivated information model for e-learning modules. Our model has proven useful for (1) the story board-based **specification** of e-learning modules, in particular the definition of forms, (2) the **implementation** of modules, specifically the enhancement of XML languages in terms of didactical structures, (3) the development of an appropriate **presentation** framework supporting the learner's orientation and navigation. [WSK02, SFB99].

The rest of the paper is organized as follows: In section 2 we discuss the scientific background of our model, section 3 presents our model in detail, section 4 discusses related work and section 5 concludes with a summary of our achievements.

2. Prerequisites and Foundations

The model presented in this paper is based on the didactical framework of Instructional Design (ID) [M94]. The focus is on the analysis and design phase of ID (i.e. preparing the learning content and planning the instructional method and media) rather than on the other processes of ID.

Prerequisites of the reference model

The model concentrates on the structure and optimal presentation of learning material on the web with minimum requirements regarding the technical and social learning environment. The basic assumptions are as follows:

Domain: Our goal is to provide online modules which accompany university lectures in technical subjects (such as maths, computer science). The domain to be taught is well structured. Scientifically founded expert models exist and are taught to the students. A collection of objectives is given (e.g. based on examination regulations) or can easily be defined.

Target Group: The target group is relatively homogeneous and their profile (characteristics, pre-knowledge) well known. Our model does not (yet) address the personalized presentation of course material with respect to different individual profiles.

Learning Situation: The main purpose of the learning modules considered here is the support of self-motivated study and unsupervised revision before exams. It is further assumed that the individual study is the primary learning form. Students may of course build learning communities on their own initiative. However, group work and communication processes are not specifically addressed in our model. In this sense our model could be seen as a part of a larger complete model [SFB99, K01].

Medium: On the technical side the minimum requirement is a standalone standard PC. A permanent internet connection, special tools or learning environments may be useful for certain modules, but are not imposed by our model.

Instruction Models

Several learning theories have been discussed in the literature as a basis for the instructional method: The major strands are **Behaviourism**, **Cognitivism**, and **Constructivism** [GCR96, M94, D92].

The constructivist learning theory is a modern approach for designing learning material as it stresses the **active individual exploration** of the domain to be studied. However, we have chosen the cognitive approach as the basis for the structural model:

- The focus is on lectures based on scientifically founded complex expert models. It is mandatory that students understand the subject in detail and on a rather formal level. The course leads the students to a high level of mastery of **predefined** objectives.
- The learner needs to receive sufficient guidance by the predefined structure and presentation of the course material since we assume unsupervised study as the main purpose.
- Even cognitively designed web material does not necessarily limit individual, active exploration when presented in conjunction with free navigation support, search facilities and integration of runtime systems (such as web-interfaces to databases, applets simulating algorithms…).

Structural requirements for online material

We have selected and categorised the guidelines from software ergonomics and media didactics related to the identified major problems of web based learning [KS88, M93, Mea96, MDC84, B97]:

Loss of overview:

1) *First present the overview then the details.*
2) *Restrict yourself to significant information.*
3) *Offer orientation opportunities to the user.*

Short attention spans:

4) Make the (re-)start of learning easy: *provide contextual information.*
5) Keep in mind, the learner will get tired quickly: *don't present too much at once.*
6) However, try to prevent the user from getting tired quickly: *activate the learner regularly.*

Why are these guidelines difficult to meet? In conjunction with formal content they lead to the following contradictive requirements:

- *Formal precision and completeness of the material vs. lower attentiveness of the recipient on the web.* Higher education often requires completeness of the material regarding formal definitions, arguments, proofs. However, when presented on the web in the wrong way certain formal material may constitute an unnecessary obstacle for the recipient's overview and flow of learning.
- *Fine-granular structure of material vs. avoiding loss of overview.* Due to the low information density the chunks of information presented on the web need to be relatively small. This leads to a fine-granular and deeper hierarchical structure as compared to print material and makes it harder for the student to keep the overall overview.

Material which is structured according to our model will automatically fulfil the guidelines stated above and thus also solve the stated contradictions.

3. Didactical Structures of Online Material – Information Model

Next, we present the model of didactical structures of courseware. The main emphasis is on the micro-structure level of *learning resources* (in contrast to macro-structures such us curricula, courses) [AD01].

Hierarchical sequential organisation

Basic entities of our model are the learning module and the learning unit.
Learning modules present instructions for learning an expert model in a single, self-contained and complete area of a certain domain. They can be (re-)used in several different courses/curricula. In our model we assume that a learning module requires 2 to 10 hours of study. Learning modules are described by metadata and organised in **sections** which represent the hierarchy of topics to be taught in the module.
A **learning unit** is a special type of section. It represents all the material and instructions required for one single learning session. The required study time is suggested to be 45 minutes.
Learning units lead the learner from one level of expertise to the next in one or more **learning steps**. Learning steps constitute one part of the learning unit's complex internal structure which is presented in the following sections.

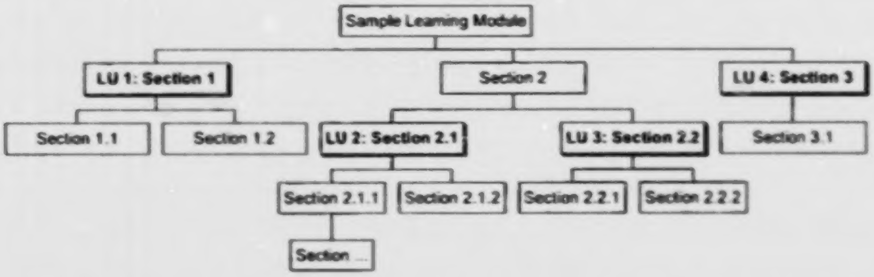

Figure 1: *Hierarchical sequential organisation of a learning module in sections and learning units*

We organise a learning module hierarchically in sections according to the logic of the instructions to be presented, **and** sequentially according to the identified learning units [R99]. The logic of instruction corresponds to the skills of the target group identified in the analysis of situated items.
Note: We do not assume that there is only one possible hierarchical, sequential organisation of a module. Different organisations may be defined manually or automatically according to the learner's prerequisites, amount of study time and individual objectives. However, for a given instance of a learning module we suggest an ordered tree as the appropriate organisation.

Horizontal Micro Structures – Information Model of Learning Unit

In this section we present the horizontal organisation of learning units due to a sequential order of didactical units in contrast to the vertical organisation discussed in the next section.

A learning unit consists of two basic concepts: didactical metadata and didactical units.
Didactical metadata contains helpful information about a learning unit to support the learner in finding the appropriate learning unit, getting started with learning and navigate efficiently through the presented material according to individual objectives. On the authoring side, didactical metadata serves as an abstract specification of the learning unit stating its objectives and relationships to other learning material, the user profile, and the external learning environment.
Didactical units represent the instructional content to be worked through by the learner. They implement the instructional design of the learning unit. Didactical units are ordered sequentially within a learning unit.

Content units in our context are chunks of information of any granularity and any type. Didactical units and their substructures **are** content units and may **contain** further sub-units at a lower level of granularity.

Didactical Metadata

We propose three categories of didactical metadata supporting the orientation of the learner.

- **prerequisites**: requirements concerning the learners profile (knowledge of certain material and keywords, level of mastery of previous objectives).
- **objectives**: learning targets of the current learning unit according to Bloom's taxonomy (knowledge, comprehension, application, analysis, synthesis, evaluation) [B56].
- **related** material: references to material which is in any sense related to the content of the current learning unit or the process of working through it. The target of these references can be internal (within the current learning module) or external (e.g. other web sites), online (URLs) or offline (e.g. books), content (web sites, books) or software (tools, simulators, programming environments) or physical elements (e.g. tools for conducting an experiment).

  Categories of related material are resources (references or tools necessary or helpful to work through the current learning unit), continuations (possibilities to continue the study besides the immediately following learning unit), extensions (references to material which extend the content of the current learning unit, and generally related material (study material with similar content, objectives or focus).

Objectives play a central role in the didactical design of learning units. According to the general model of instructional design we suggest to specify the objectives of a learning unit first before specifying its didactical units. When specifying didactical units the objectives are linked to the relevant content units or test questions within the learning unit. Thus a bipartite graph as depicted in figure 3 is defined between content units and associated objectives [G89].

content unit B
test question I
content unit C
test question II

Figure 3: Bipartite graph of objectives and units of contents / test questions

Regarding the manifold functions of objectives we refer to the discipline of instructional design [M94] and add the following:

BEST COPY AVAILABLE

- Objectives - when associated with content units - can serve as an additional, goal oriented navigation structure.
- They serve as an indirect association mechanism between different content units as well as between content and test questions. Content units associated with the same objective are similar according to this objective. This is particularly useful in relating test questions to relevant content. In figure 3 the relevant text passages for test question I are content unit A and B. If the learner has problems in answering this question the test system can direct him/her to the related material.
- As stated previously, objectives can be interpreted as an abstract specification of the learning unit. The association between objectives and content to some degree enables the formal verification of a given implementation. In figure 3 objective 4 is not associated with any content unit, thus there is obviously no course material present which could enable the learner to achieve objective 4. A processor examining the associations between objectives and content can automatically identify these possible structural problems.

Didactical Units

Didactical units implement the instructions of a learning unit w.r.t. its objectives. They contain

- **overview information** presented in the introduction and conclusion.
- **detailed information** about the concepts to be studied as presented in the learning steps.
- **exercises** and **test** questions presented in the training section.

The aim of the **introduction** is to (1) **get** the learner **started** by stating the textual context of the current learning unit within the module (initial situation), (2) **activate** the learner by defining the problems to be solved within the current learning unit (problem description), (3) **motivate** the learner (motivation), and (4) **guide** the learner by giving specific instructions of how to work with the following material (instruction).

Learning steps present the details of the concepts to be learned. We suggest to divide the material of a learning unit into 3 or 4 learning steps each about 10 to 15 minutes in length as this is about the average attention span for picking up new information on the screen [KS89]. A learning step is divided into a small number of substeps. After working through the substeps the user is directed to an assessment screen containing a small number of relatively simple self test questions. These questions activate the learner and provide regular and immediate feedback regarding the learning progress.

The **conclusion** puts the details presented in the learning steps into an overall context of the learning unit by (1) **repeating** the essence of the concepts studied in the previous learning steps (summary), and (2) **motivating** the learner to continue studying the following learning unit (outlook).

The **training** part plays a central role in learning. Its aims are:

- Building up a high level of mastery of the defined objectives through active reproduction and application of the concepts studied in the learning steps (exercise).
- Self-test and feedback regarding the degree of mastery of the objectives (assessment).

It may be desirable that some exercises such as formal proofs, programming or software design are done offline or using specialized tools. While these exercises can be listed in the exercise section of a learning unit the execution, submission, assessment and feedback is out of the scope of the model.

Current e-learning and CBT systems provide a large variety of tools and information models for computer based online/offline training and assessment [QTI02]. We do not suggest yet an another information model but assume, that one of the existing formats is adopted according to local requirements (installed e-learning platform and assessment tools). The entities exercise and assessment in our information model serve as an abstract placeholder for one of these local information models.

Presentational Design

Presentational design adds annotations to the didactically structured material such that the material can be optimally presented as web-pages with respect to the special limitations (low information density) and advantages of the medium web (linking, interactivity).

Presentation Units

The concepts presented so far were merely motivated by the didactical function of the content. Presentation units are motivated by the characteristics of the medium web. A **presentation unit** represents the content of one single web page. Its size should be small enough to avoid scrolling [B97].

Ideally, presentation units can be defined along didactical structures such as introduction, substep, or summary. However, it might be appropriate that a complex substep spans several presentation units or that several small substeps are covered by a single presentation unit.

***Figure 4**: Hierarchical sequential structure of a learning module after definition of presentation units*

The module is organised as an ordered tree having presentation units as leaf nodes. Sequential orders are defined at the level of learning units and at the level of presentation units within learning units. This two-level sequential order serves as an ideal address base. Every page within the learning module can be identified by two numbers: the number of the learning unit and the number of the presentation unit within the learning unit. This is useful for the **orientation** of the learner ("Where am I?") and for precise **communication** for example in giving feedback ("Don't understand definition in LU 3 / PU 5").

Vertical Micro Structures – Presentation Levels

Besides the didactical function of content we identify two subsidiary structural dimensions: (1) **importance** of content regarding the objectives to be achieved, and (2) **difficulty** of material for the average learner.
Related to these dimensions we can define three distinct *presentation levels* as follows:

- Content units, which are important and relevant regarding one or more objectives, belong to the presentation level **basic**.
- Content units, which are less important or relevant **and** can be assumed to be known or self explanatory for the majority of the target group (low difficulty), belong to the presentation level **help**.
- A content unit is assigned the presentation level **extension** if it is less important **and** difficult to understand for the majority of the target group (e.g. due to its high level of abstraction and formality).

BEST COPY AVAILABLE

By revising the material and assigning presentation levels to content units the following is achieved:

- The content of the basic presentation level is concise and highly focussed on current objectives.
- The novice user can access additional information at the help level on demand.
- The experienced or specifically interested user is offered additional opportunities in deepening his / her knowledge by pursuing extension links.

4. Related work

Pedagogical theories and models proposed in the literature are manifold [K01]. As a result existing formal models of courseware take up a rather abstract point of view in order to be valid for all kinds of learning situations and didactical strategies.

The CAMELEON project aims at providing reusable modules for online/offline course materials encoded in TeachML [WL01]. TeachML identifies several didactical units (such as examples, figures with explanation, exercises) and structures such as (courses, chapters, learning paths, ...). However, an underlying didactical model or design strategy is not visible. As a result TeachML gives little assistance in *how* to use the provided elements in order to develop learning material which can optimally be presented and studied on the web.

The "life long learning" project aims at meeting the needs of different target groups by offering several learning trails through the same online course specified in the XML language L3-XML [SLK00]. L3-XML introduces the notion of a learning unit (LU). Similar to our approach each LU contains objectives and all information necessary to achieve them. However, in L3-XML a LU is a recursive element in order to specify the hierarchy of topics presented in a course rather than a precise didactically motivated information model for a single learning session.

The EML [K01] provides a framework for the complete XML-based description of all objects, roles and activities involved in the teaching/learning process of a unit-of-study. EML is an XML-binding of a pedagogical meta model and thus stays abstract regarding the specific instructional / pedagogical model to be adopted when implementing a unit-of-study. Our specific didactical model can serve as a possible instantiation of the EML meta model for cognitively organised instructional material. It can be integrated into EML (and other existing mark-up languages) by using subtyping as suggested in [K01] and already successfully implemented on the basis of LMML [SFB99, WSK02].

5. Conclusion

We presented a reference model for structuring online modules in formal and abstract domains such that the learning content can be optimally presented according to the characteristics of the medium web. We have shown how to tackle two problems inherent to web based material – loss of overview and short attention spans – by satisfying the following structural requirements: (1) *first present the overview then the details* (introduction), (2) *restrict yourself to significant information* (presentation levels), (3) *offer orientation opportunities* (two level sequential order of learning units and presentation units), (4) *provide contextual information* (introduction, summary, objectives associated to each presentation unit), (5) *Don't present too much at once* (small learning units, learning steps and presentation units), and (6) *regularly activate the learner* (each learning step of 10-15 min ends with a self-test).

Our approach is different and innovative as compared to other approaches because

- we identify the didactical components of courseware on the microstructure level and suggest precise qualitative and quantitative guidelines based on research results.
- we distinguish three presentation levels as an additional dimension of structuring online material, which help to focus on essential information while maintaining the formal completeness of the material.
- we do not only introduce didactical metadata such as objectives as useful concepts in organising and managing learning material, but also suggest association of objectives and learning content/exercises to provide a goal-orientated navigation facility and to define indirect associations between single content units of the learning module.

An XML-Binding of our model is currently integrated as a possible didactical component into the LMML and WWR-ML frameworks [SFB99, Dea02].

Abstract: The past 8 years of growth of the Internet and computing have brought unprecedented change in the U.S. education system. Between 1993 and 1999, the percentage of schools with access to the Web grew from 35% to 95%. and classrooms with Web access increased from 3% to 65%. By fall 2000, the ratio of students to instructional computers was 5 to 1, as compared with 20 to 1 in 1994. During this time, the nation has invested over $38 billion to bring educational technology and Web connectivity to America's schools. But despite this boom, inadequate resources have been devoted to establishing empirically whether or not, and how, the Web is an effective instructional tool. This paper discusses a literature review of over 300 research articles in Web-based learning between 1993 and 2002. The conclusion is reached that empirical research into Web-based learning is severely wanting. A research agenda is proposed based on trends and themes emerging from the papers we reviewed.

The past 8 years of growth of the Internet and computing have brought unprecedented change in the U.S. education system. Between 1993 and 1999, the percentage of schools with access to the Web grew from 35% to 95%. During the same period, classrooms with Web access increased from 3% to 65%. By fall 2000, the ratio of students to instructional computers was 5 to 1, as compared with 20 to 1 in 1994. During this time, the nation has invested over $38 billion to bring educational technology and Web connectivity to America's schools rising from a mere $46 million of funding in 1995, to over $3 billion this year through a range of federal programs. There is every indication that these levels of investment will continue.

Now, a decade after the introduction of this technology, industry estimates suggest that over 500 Million people worldwide are using the Internet (Nua Internet Surveys, 2002). At the same time, a large number of corporations, institutions of higher education, government organizations and non-profit organizations are beginning to embrace the Web for the delivery of training and instruction, naming it "the next major killer app".

Given this high number of individuals with Internet access and the growing interest in using the Web for instruction, the question arises as to what research has been carried out on the effectiveness of Web-based delivery of instruction.

Research Objective

In the review of the literature for this article we will focus on three questions:

(1) How is the Web currently used for instruction, as reflected in the literature?

(2) What types of empirical inquiries are employed to study the use of the Web for teaching and learning?

(3) What evidence for the effectiveness of the Web for teaching and learning is reported?

Method

The literature reviewed for this article included academic journals and conference proceedings in the field of education, educational psychology, and instructional technology. We reviewed a total of over 400 articles from over two dozen journals and conference proceedings. In a first pass, we reviewed the titles of the articles that appeared in each publication since the establishment of the Web in 1993 through they year 2001. We filtered out articles that could clearly be identified as not concerning the Web. In a second pass, we selected articles to be included in the review based on the contributions they made to the discussion of our three research questions.

Findings

Of the papers that we identified as related to the use of the Web for learning and instruction, the vast majority (63%) was of a non-empirical nature. These non-empirical papers were either conceptual articles, discussing design guidelines and theories, prescriptions for the use of the Web in learning and instruction, and taxonomies for Web-based instructional materials (36%), described software, projects, tools, and models (26%), or reviewed the existing literature on Web-based learning (1%).

The majority of articles originated from practitioners of various subject-matter areas who reported on their use of the Web for learning and instruction, rather than from educational or psychological researchers. The most common subject matter used as instructional content for WBI systems included multimedia, Web, computer science, and sciences (especially biology, chemistry, and engineering), which, taken together, accounted for over a third of the subject areas being taught. Mathematics, non-science subjects such as literature or public policy, languages, and music were the subjects taught in just under a third of the WBI research we reviewed. Examples of the less frequent subjects taught by WBI systems included operations management, nanoscience, drug prevention and civics studies. Humanist or esoteric subjects such as philosophy, religion and poetry were notably absent from our sample, although no research was identified which analyzed the differential effects of WBI across different subject areas or topics.

The vast majority of developmental research papers we reviewed described WBI systems which utilized some form of communication systems. Most researchers now emphasize the important role that the Web plays in supporting communication and collaboration among learning teams through email, synchronous or asynchronous chat tools, or in some cases, more advanced conferencing or whiteboard tools and they developed WBI systems built largely around these communication functions.

Most researchers engaged in exploratory or descriptive research, the typical example of which are program evaluations and exploratory survey studies. We found only a very limited number of articles describing naturalistic inquiries and case studies, which is surprising considering the ill-structured nature of the field of Web-based learning and the apparent need for hypothesis-generating research. The low number of explanatory research on causal relationships we found may reflect the fact that the theoretical basis of the use of the Web as an instructional medium is as of yet underdeveloped. The experimental/quasi-experimental studies that we found focused on comparison of Web-based delivery of entire courses with other, traditional delivery formats, or on specific strategies of Web-based instruction, such as computer-mediated communication.

The effectiveness of the Web in instruction was often found to be expressed simply in terms of the *enthusiasm* it generates, the motivation to learn, explore and to participate - on the part of "innovative" teachers as well as learners. The effectiveness of the Web in instruction was also found to be expressed in terms of its much touted "promise": increased access to learning; more personalized learning; more individualized learning; stimulation of collaboration and cooperation of all participants at all levels; empowerment of learners; increased accountability; increased currency (up-to-date) of content; increased efficiency and effectiveness of education; reduced costs; reduced learner time to competence; and rapid adoption of new information and new programs. Our review found many such discussions of these promises, but little meaningful research, evidence or discussion of these promises' relationships to actual gains in academic performance or overall intellectual growth. This "promise" conveys rather, a complete transformation in how the time devoted to learning is spent. Whether or not this brings about improvements in learning performance is usually not addressed.

The effectiveness of the Web in instruction was also discussed in terms of the many diverse functions and functionality of Web-based learning environments, tools and toolsets. From chat, e-mail, images and sound, file sharing, to Web-conferencing, application sharing, electronic whiteboards, and more recent broadband interactive multimedia tools, the Internet has offered a seemingly compelling high-tech toolkit that, though dizzying in variety, is *presumed* to boost learning and instruction. Many researchers would write as though the mere *bundling* of a wide range of tools was pedagogically beneficial in an of itself – the large number of papers written *by* computer scientists *about* computers, multimedia or the Web testifies to this.

Although the research papers we reviewed tended on the whole to be enthusiastic and encouraging about the use of WBI, around 10% of the papers sounded a cautionary – and in some cases, a critical – note about WBI. This wariness showed itself as arguments for the need for a stronger theoretical basis for WBI and a more developed program of fundamental research in WBI, to criticism of the commercialization of WBLEs. Other concerns included the argument that heightened interactivity and visually rich learning resources may not actually aid learning but rather distract, or that hypermedia authoring systems often do not provide functionalities required for true constructivism. Moreover, students still expect to emulate the traditional lecture paradigm online and do not exploit the unique characteristics of WBLEs. Researchers comment that WBLE design takes time, money, and specialized skills and there are usually few shortcuts.

Indications of Future Research Efforts

A wide range of potential research avenues are described by researchers in varying degrees of formalism. By compiling these indications, a glimpse of an overall research framework emerges.

The most frequent research focus in the developmental research papers involved aspects of the complex relationships between, knowledge, mental models and conceptual structures on one hand, and hypermedia navigation and interface design on the other. Much needed research on the theoretical basis for WBI design, development, delivery, evaluation, and learner assessment was also cited frequently in the research we reviewed. Studies of learner collaboration and patterns of learner interaction in WBLEs were also cited frequently, as was research into the relationships between individual differences in/or learning styles with WBLEs. Research into authoring tools and delivery systems, as well as research into learning strategies in WBLEs were commonly mentioned. Authentic, meaningful Web-based learning tasks, the use of authentic technologies and their translation into design principles was another topic requiring further research. More exotic applications of the Web such as immersion and virtuality were also seen as fruitful research areas. Standards and interoperability, learner control, metacognition and complex thinking in WBLEs, as well as cognitive tools, specialized digital learning tools, and teaching tools for specific subjects, were also cited as areas for further research.

Title: Tools of the Web-Based Learning Trade

Introduction

Tools have been integral to all advances of humans since the beginning of time (Rosenberg, 1976). Tools of the agricultural age were the ploughs, the industrial age was the metal implements, and the information age is the computer. These tools helped in the advances of mankind by improving productivity as well as changing the nature of the tasks. Rosenberg (1976) suggests that the fundamental unit of change in all tool effects is how each individual learns to use the tools, improves the use of the tool, and invents new tools resulting in economic development over time. Following that same thinking to the information age focuses our attention on the computer as THE tool of our day. Computer tools have become a part of everyday life today and has become the key to work, play, and learning activities. We use computer tools like databases, spreadsheets, and the World-Wide-Web in most activities today.

The focus of this paper is web-based learning environments and the tools that can support learning. This paper argues that the tools of web-based learning should be the tools that support problem solving and not the tools of course management.

We begin with a theoretical foundation of tool effects on humans, overview of research on how computer tools affect learning and how this information should influence the web-based learning environment, and conclude with two examples of computer tools used in web-based learning.

Theory - The *Effect Of* and *Effect With* Tools

Pea (1985) presented two components of tool effects on humans. First, he suggested that as humans use tools for their activities the tool leaves a cognitive residue on the person using it. This cognitive residue was termed the "*effect of*" computer tools. Salomon et al. (1989) presented findings that showed how learners internalized prompts from a reading partner to improve their reading and monitoring/understanding skills. As learners were given prompts to attend to the main points of the reading, they were able to improve their understanding of the material and were able to transfer the skills to other reading activities. Here the *effect of* the tool was the students' display of the monitoring skills prompted by the reading partner.

Second, humans solving problems with tools is described as the *effect with* tools (Pea, 1985). The *effect with* tools is a complex phenomena where humans can off-load working memory intensive mental activity to a computer tool and concentrate on higher-order thinking and the tool provides an affordance to the activity. Off-loading is a simpler concept where users can overcome limitations of working memory by allowing a spreadsheet to do calculations while they concentrate on higher order activities like hypothesis testing (Salomon, 1990; Salomon et al. 1991). Affordances on the other hand are complex interactions that are affected by the tools, the prior knowledge of the users, and the types of activity where the tool is being used (Gibson, 1966; Greeno, 1994). For example, Zhang (1997) showed that users are affected by the presentation modes and think that one type of Tic-Tac-Toe presentation is more complex than others. Similar findings were report by Kozma & Russell (1997) where younger novice learners were more affected by representations of problems than experts.

The combination of the *effect with* and *effect of* tools has very important implications for the design of web-based learning environments. The computer tools can and do have lasting impacts on the knowledge structures of learners, and these experiences have the potential to affect their future work and learning activities. The research supporting this theoretical framework is described next.

Research - A Summary

The *effect of* computer tools have been studied in the areas of reading (Salomon et al. 1989), writing (Salomon, 1993), mathematics (Adams & Shrum, 1990; Dixon, 1997), science (Roth, 1995), and many others. The findings of these studies are mixed. Wijekumar & Jonassen (2002) presented findings showing how the *effect of* long term computer tool use was evident in experts' problem schemas, approach to problem solving, and the solutions as well.

The *effect with* computer tools also has some very relevant findings. Wijekumar & Jonassen (2002) report how experts interacted with the computer tool to off-load some mental activities like calculations, graphing, and statistical analysis, while they concentrated on identifying the possible factors that explain the results as well as comparing the results from different types of analysis. Roth et al. (1996) however showed that younger learners had difficulty in using the tools because they lacked the prior knowledge and knowledge of the tool's use to effectively accept the affordances provided by the tool.

In summary, research has shown that computer tools do leave a cognitive residue on its users in their problem schemas and knowledge structures. It is also becoming evident that the tools interact with the users providing very complex affordances which are dependent on the prior knowledge and experiences of the users. Based on the research reviewed the following are critical aspects of computer tool use in educational settings.

1. The tool(s) will leave a cognitive residue on the learners
2. The tool(s) should provide the scaffolds and support the learning process as it relates to the goals and objectives of the learning environment and tasks.
3. The tool should also be introduced to help the learners learn and as an assessment tool. It should not be assumed that learners have the domain knowledge and/or tool skills to use the tool effectively.

Given the state of theory and research on computer tools in human activities do we have the right tools in our web-based learning environments?

Web-Based Learning - The Tools

The current rage in web-based learning environments is the use of course design and management systems that are sometimes also referred to as learning management systems. Examples of these products include WebCT, BlackBoard, etc. These environments provide a general framework to allow designers and professors to create on-line courses which contain notes, multiple choice tests, essay tests, links to web sites, chat rooms, bulletin boards, and email. While these are some tools for creating web-based learning environments, they are frequently the only tools available to designers, professors, and learners. A review of any journal on web-based learning and/or papers on the topic shows a variety of topics on comparing web-based courses with in-class courses, studying the discussion contents of bulletin board postings, and analyzing interactions of learners using the same.

Reading these papers makes one want to believe that learning can occur through reading notes, conversations (bulletin board and chat), and/or multiple choice tests only! Tools have been shown to leave a lasting imprint on the knowledge structures of learners and this impact affects future problem solving as well. If students were reading notes, posting comments, and taking tests, what types of knowledge structures can they be expected to have? Are they using the tools that are appropriate for the task? How are they using them? What scaffolds are being used with the tools?

In light of the research and theory discussed in this paper it should be obvious that these web course management tools do not address these concerns and they are not and should not be the only tools of the trade for a web-based learning environment. To be an effective environment for learning it is critical to address the following factors:

1. The right tool for problem solving must be used by the learner
2. The correct scaffolds and help for using the tool should be available to the learner
3. The assessment of the learning should include the use the tool.

Next we present two examples of how tools can be integrated into web-based learning environments to facilitate learning.

Examples of Effective Use of Tools in Web-Based Learning Environments

Case 1

A graduate level course on management economics requires students to analyze data on employee performance to recommend a reward program for a company. As part of the case students on the web are required to read the literature on performance factors as well as incentive and rewards programs. The next step is to provide the student with a statistical analysis tool to perform the analysis themselves.

As part of the course design a Filemaker Pro database was linked to the case study and instructions and guidance was given on the use of the tool. The student was also able to keep open two windows, the first with the database/analysis tool and the second which contained instructions and feedback based on their responses from the analysis.

The important points in this example is that the users had access to a real tool which was used as part of their problem solving activity. They also responded to questions in the second window which was written using a CGI-SCRIPT so that they could submit answers to the system and get automatic feedback on their answers as well as possible next steps. This combination provided the students with the correct tools as well as the scaffolding necessary to use the tools.

Case 2

An undergraduate level course on distributed programming provided a comprehensive enterprise level development environment linked to the course. This environment used open source software Ant, Tomcat, Jboss, XML, and HTML, which was structured so that learners could build, deploy, and test their enterprise application using Java™ in a controlled setting with scaffolds. For example, the learners were given written guidelines and a tutorial on creating, testing, and deploying servlets and linking the servlets to web pages. The students used the pilot environment to develop their solutions using multiple levels of input from the system as well as the instructor, and colleagues. The users had access to the complete sets of instructions, examples of deployed servlets, hints, and access to logs. The environment was set up with secure access from anywhere using a Secure Shell Application and Protocol.

Implications for Designers of Web-Based Learning Environments

The examples presented here were designed to showcase how computer tools can and must be incorporated into web-based learning environments to support the most realistic problem solving environment. The choice of tools depends on the tasks and objectives of the course.

The current array of web-based course management tools are not sufficient to develop a learning environment that supports the construction of problem solving and other complex skills. It should be the designer and/or creators responsibility to identify the tools required and choose the interfaces as well as the implementations that will seamlessly provide access to those tools.

The access methods described in this paper required programming expertise in web related programming and markup languages like html, xml, CGI scripts - Perl, and understanding of the hardware requirements for supporting the course content, layout, and delivery. Building scaffolds adds another level of complexity by requiring a complex thought process on how novices learn, identifying the types of hints they will need, and designing the interface that will provide the scaffold and not be too intrusive in the learning process.

Conclusion

As shown in the examples, the tools of web-based learning should be chosen based on the goals of the course and individual objectives. If a student in a web-based course is learning to create an incentive plan for employees of a company, then they should be given access to the tools that facilitate the tasks that support the objectives. If a student is learning to create a web-based bookstore then they should have the tools and resources necessary to create programs, test them and showcase them. These and many other examples in human services, Physics, Mathematics, and Law will be presented at the conference to showcase how we can improve the cognitive residue of our web-based learning environments and change the nature of the tasks by allowing the learners to off-load mental work to the tool and accept the affordances provided by the tools. These should be the tools of the web-based learning trade.

Integration of e-Learning and Knowledge Management

Abstract: e-Learning technology today is used primarily to handcraft training courses about carefully selected topics for delivery to employees registered for those courses. On the other hand, knowledge management technology is used to rapidly capture, organize and deliver large amounts of corporate knowledge. This paper investigates the integration of e-learning and knowledge management technology to improve the capture, organization and delivery of both traditional training courses and large amounts of corporate knowledge. First, a model is proposed for the phases of knowledge management. That model is then enhanced with concepts and technology from e-learning. The model is then used to illustrate four real world scenarios that add increasing amounts of knowledge management to an e-learning environment. Analysis of these four scenarios will help to better understand the practical relationship between knowledge management and e-learning.

1. Phases of Knowledge Management

One way of understanding the impact of knowledge management on a corporation or government organization is to look at the knowledge management lifecycle and the flow of knowledge in the organization. Nonaka and Takenuchi (Nonaka & Takenuchi 1995) have investigated the relationship between tacit knowledge and explicit knowledge and have described four phases of knowledge conversion: Socialization, Externalization, Combination and Internalization. The goal of the implementation of knowledge management in an organization is to increase the amount of tacit knowledge that an individual has available to apply to solving business problems. This suggests that there is a fifth phase, Application, which is the application of knowledge that has been exchanged through the other phases (Frappaolo & Toms 1997). These five phases are described below and illustrated in (Fig. 1).

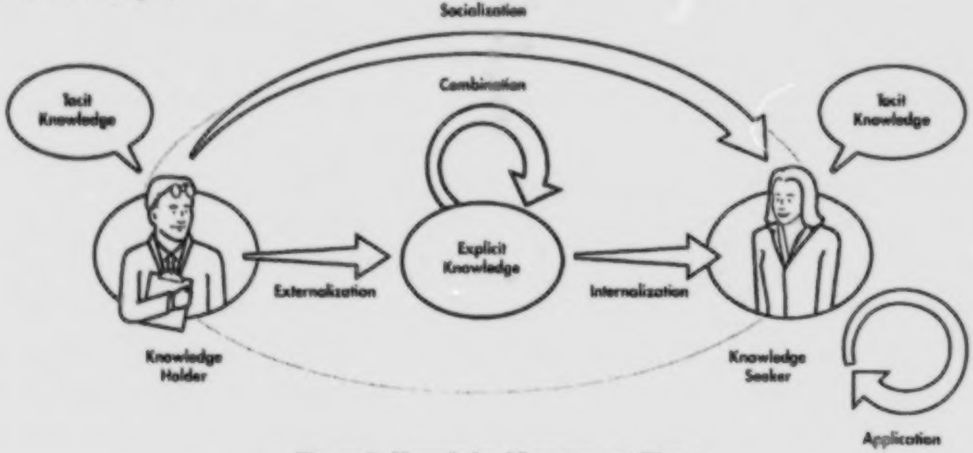

Figure 1: Knowledge Management Phases

BEST COPY AVAILABLE

- **Socialization:** Transfer tacit knowledge from one person to another person
- **Externalization:** Translate tacit knowledge into explicit knowledge in a repository
- **Combination:** Combine different bodies of explicit knowledge to create new explicit knowledge
- **Internalization:** Extract the explicit knowledge from a repository that is relevant to a particular person's need and deliver it to that person where it is translated into tacit knowledge
- **Application:** Apply tacit knowledge to a business problem

2. e-Learning Enhancements to Knowledge Management

e-Learning technology has been evolving separately from knowledge management technology. There have been recent investigations into the integration of these technologies (Barron 2000) (Allee 2000). e-Learning technology will enhance the effectiveness of each of the five phases of knowledge management as shown below. A sixth phase, Feedback, has also been added.

- **Socialization:** Competency and skills measurements help identify the people with specific interests, skills and knowledge in the organization.
- **Externalization:** Knowledge is captured by the system with the intent of teaching that knowledge to other people. This improves the knowledge capture process.
- **Combination:** Knowledge about products and processes of the business is organized to make learning the knowledge more effective and efficient. Pedagogical techniques are embedded in the knowledge.
- **Internalization:** Competency and skills measurements help identify which people lack the knowledge to do their job effectively and provide them with online training. e-Learning will insure that a person has learned the knowledge using assessments and alternative learning methods, if necessary.
- **Application:** People can be provided with on demand performance support by getting just the training that they need at the time that they need it to complete a business task.
- **Feedback:** Assessments provide feedback concerning how well a person has learned and how well they have applied what they learned to a business problem.

(Fig. 2) is a modified and more detailed version of (Fig. 1) that represents the knowledge management phases with e-learning enhancements. In (Fig. 2), a Knowledge Holder can either transfer tacit knowledge to a Knowledge Seeker through socialization or create explicit knowledge and store it in a knowledge repository. The Knowledge Organizer in (Fig. 2) is a person (or software program) who relates the created knowledge to other knowledge in the repository or further refines the created knowledge. The Instructional Designer is a person (or software program) who organizes the learning of the knowledge by adding pre-assessments, additional learning aids, and post-assessments. The Knowledge Seeker then learns the explicit knowledge through an online guided learning experience. The Knowledge Seeker then uses the knowledge gained through socialization or internalization to make decisions and perform tasks in the enterprise. The performance of the Knowledge Seeker on these decisions and tasks is measured and returned to the knowledge repository as feedback that can be used to help determine if the skills have been learned and to suggest additional e-learning experiences.

The implementation of these knowledge management phases with e-learning enhancements will require new advancements in technology. The application of new technologies such as semantic web services, competency ontologies, business process integration and intelligent software agents within an enterprise is discussed in (Woelk 2002). The application of these technologies across multiple corporations, educational institutions and community organizations in support of performance-based lifelong learning is discussed in (Woelk & Lefrere 2002).

3. Business Scenarios

This section illustrates the integration of knowledge management and e-learning through the use of a series of four business scenarios. The scenarios represent the addition of increasing amounts of knowledge management concepts and technology to an e-learning environment.

Figure 2: Knowledge Management Phases with e-Learning Enhancements

The first three scenarios concentrate on increasing the effectiveness of the performance of employees in meeting the objectives of the company. This requires that an employee receive the *right knowledge* at the *right time* and *just enough* knowledge that they need to execute effectively. The *right knowledge* that an employee needs is determined by their role in the company and the products and processes in which they are participating. The *right time* to receive that is knowledge is when they need it for a specific task. *Just enough* knowledge is whatever they need and nothing more. The fourth scenario concentrates on the ability of a large publisher, such to meet the future demands for the publishing of large amounts of digital information.

3.1. Business Scenario 1: Traditional e-Learning

Scenario 1 is shown in (Fig. 3). A large company has 1000 worldwide salespeople who sell 100 products. There are 1000 engineers and marketing people who create and release 5 new products (or product enhancements) per month. There are 5 instructional designers who collectively build 2.5 online courses per month that are used to train salespeople on new and modified products. These are simple 2 hour courses that concentrate on information transfer rather than skill development. Instructional designers will typically talk to engineers and marketing people to find existing online content or to learn enough to create the learning content themselves. Learning objects (Longmire 2000) are created that may be stored in a Learning Object Repository so that they can be reused in other courses. This helps when new courses are created for existing products but does not help much when courses are created for new products.

The company encounters the following problems with Scenario 1:

- There is content that the instructional designers don't know about that could be used in courses.
- There is content that the instructional designers know about but they can't find. Even if they find content, it might be incorrect.
- Instructional designers don't have time to talk to all of the engineers and marketing people so they produce fewer courses.
- The 5 instructional designers can only build a total of 2.5 courses per month so some products introduced each month no not have a training course.

Figure 3: Scenario 1: Traditional e-Learning

3.2. Business Scenario 2: e-Learning Based on Enterprise Content

Scenario 2 is shown in (Fig. 4). In this scenario, the company uses a Content Management System to create, store and update the content about new products from the 1000 engineering and marketing people. This increases the effectiveness of the instructional designers because they can build learning objects by finding and reusing the content created by engineering and marketing. By building learning objects in this manner, the content of the learning objects can automatically be updated when the content in the Content Management System is updated. These improvements will enable the 5 instructional designers to create a total of 5 courses per month.

However, the company encounters the following problems with Scenario 2:

- Courses are created using smaller, reusable learning objects, but entire courses, not individual learning objects, are delivered to sales people.
- People in the company are creating knowledge about the products that is not being embedded in the courses. Email messages, memos, sales call notes, audio messages, meeting notes, product recalls, customer support problem reports, personnel and strategy changes at customer companies, etc. all contain knowledge that would make the sales person more effective.
- Sales people either never know that this knowledge exists or they spend valuable time interacting directly with engineering, marketing and other sales people to find the knowledge. Even then, they might interact with the wrong person and get the wrong information.

Figure 4: Scenario 2: e-Learning Based on Enterprise Content

3.3. Business Scenario 3: e-Learning Based on Enterprise Knowledge

Scenario 3 is shown in (Fig. 5). In this scenario, e-learning in the company leverages not only the content in the Content Management System, but also the knowledge that has been captured in a Knowledge Management System. This knowledge includes email messages, memos, sales call notes, audio messages, meeting notes, product recalls, customer support problem reports, personnel and strategy changes at customer companies that were mentioned in the previous section. But the knowledge also includes information on the roles, skills, expertise and performance of individual employees that will simplify the transfer of tacit knowledge and explicit knowledge to the sales person. This knowledge will enable the sales person to find the right learning objects and to contact the right people for tacit knowledge that is needed to be effective. The key to finding the right content and the right people from the multiple information sources in (Fig. 5) is an ontology containing a metadata representation of the concepts, relationships and processes of the enterprise. Progress is being made in the standardization of ontology representations (World Wide Web Consortium 2002). An enterprise ontology can provide a gateway to multiple information sources that can be navigated by people and software agents (Lenat 1995) (Woelk & Tomlinson 1994).

In this scenario, knowledge will be delivered through a variety of presentation devices including web browsers, PDA's and cell phones. This enables the sales person to receive the knowledge when it is needed regardless of where they are and what they are doing. e-Learning will be delivered as small, focused learning objects to fit the format of the presentation devices.

(Fig. 5) shows that the role of the Instructional Designer is still to organize the learning of the knowledge. But the Instructional Designers will be more efficient because the authoring systems will be more intelligent and the knowledge will be better organized. This organization of the knowledge will be the responsibility of Knowledge

Managers and automated software programs. In this scenario, 5 Knowledge Managers and 5 Instructional Designers will be able to create 1000 learning objects per month.

3.4. Business Scenario 4: Digital Publishing

Scenario 4 is shown in (Fig. 6). A large publishing company has 1000 independent authors who contribute content and knowledge to be published to a mass audience of millions of people and institutions. The contributions are in the form of knowledge objects that may be either full books, training courses or smaller pieces of knowledge. The publishing company has Knowledge Editors who organize and correlate the contributions to make them easy to find. The publishing company also has 5 Instructional Designers who may further organize some of the knowledge in order to publish it as e-learning. These authors, knowledge managers and instructional designers will be able to publish a total of 1000 learning objects per month.

This is similar to Scenario 3 except that there are additional issues:

- Knowledge is being transferred across multiple companies and individuals rather than within a single company. This includes thousands of authors and millions of readers.
- The traditional security issues of authentication, authorization, integrity, confidentiality, audit and accountability must be dealt with in a geographically distributed environment.
- The issue of digital rights management must be solved:
  - Ownership of content
  - Rights to use that content in specified contexts
  - Appropriate payment for the use of those rights
  - Security and protection required to enforce those rights
  -

- Information about the knowledge that readers already have will be used to identify the knowledge that they wish or need to acquire. This information will exist in a broad number of places such as university records systems, military training histories, company training histories and corporate ERP and HR systems.

4. Conclusions

This paper has illustrated how e-learning techniques and technology can be used to enhance knowledge management in an enterprise and provide the benefits of both. First, a model was presented for the integration of e-learning and knowledge management. The model was then applied to some real world scenarios to illustrate the benefits of this integration. These scenarios also provide a roadmap for the evolution of new systems that will provide both the efficient capture of knowledge and the efficient delivery of knowledge.

XML Based Course Websites

Michael Wollowski
Computer Science and Software Engineering Department
Rose-Hulman Institute of Technology

wollowski@rose-hulman.edu

Abstract: XML, the extensible markup language is a quickly evolving technology that presents a viable alternative to courseware products and promises to ease the burden of web authors who edit their course pages directly. XML uses tags to label kinds of contents rather than format information. The use of XML enables faculty to focus on providing contents, leaving the task of rendering contents to experts who provide a single stylesheet used for formatting purposes. This stylesheet has to be edited once, saving time and effort and ensuring consistent appearance of course pages that reference it. However, the major benefit of XML is the ability to provide pinpoint search engines. Additionally, web-based editors can be provided to make editing pages easier.

Introduction

The *Extensible Mark-up Language (XML)* is a promising new technology for creating, maintaining, and searching course pages. XML shows the most promise when it comes to searching for information. Furthermore, the use of XML reduces the overhead of editing web-pages by separating form and contents. Content providers have to do just that, provide the contents. Similar web-pages are rendered by a common stylesheet. It only has to be edited once. A common stylesheet ensures uniform appearance of web-pages that are of the same kind. This in turn provides for ease of navigation and recognition of location.

When it comes to course web-sites, there are largely two alternatives: to edit and maintain them directly or to use courseware products such as (WebCT 2002) or (Blackboard 2002). The benefits of direct editing are complete control over appearance and contents; the major drawback is a lot of work formatting contents. The benefits of courseware products are ease of use and integration with other academic systems, such as the Banner; a drawback is that formatting and functionality are as provided. We propose a third option which is slowly become a viable alternative: the use of XML. We will show in this paper that XML shares most of the benefits of the two current alternatives: ease of contents creation and maintenance as well as complete control over appearance and contents. A major added benefit of XML is the ability to furnish very precise search engines, enabling users such as students, prospective students, or prospective employers to quickly locate relevant information.

Industry started using XML a while ago, chiefly to unify information between companies and their suppliers (Goldfarb & Prescod 2000). We show an application of this technology that demonstrates its benefits for academic use. We will briefly explain the main components of XML and in the process show how XML separates form and contents. We will demonstrate how common information can be placed into separate files, greatly aiding in the maintenance and consistency of course sites. We will show how to is to provide web-based editors as well as search engines for course pages. Finally, we will report on the status of the project.

Separation of Form and Contents

XML is three technologies in one. It consists of *XML* proper, which is a language for labeling contents. There are *Document Type Definitions (DTDs)*, which are used to specify kinds of documents. Among others, DTDs specify the labels to be used in XML documents. Finally, there are languages to render XML documents. Typically, web-authors use either the *Extensible Stylesheet Language (XSL)* or *Cascading Stylesheets (CSS)*. Since XSL is more powerful when it comes to the way final documents can be composed, we chose XSL over CSS. At this point, only Internet Explorer 5.5 and higher support XSL. Most other browsers support only CSS.

In what follows, we present an example of an XML document containing a course description of one of our courses. We want to show how XML supports the separation of form and contents. The challenges of dealing with larger documents such as syllabi will be addressed in the conclusions. Figure 1 shows an XML file containing course description information for CSSE 100, one of our courses. In general, white space does not matter and should be used to enhance readability. XML *tags* are identified by opening and closing angle brackets. A closing tag is identified by a forward slash preceding its name. An opening and closing tag form an *element*. To aid in readability, we boldface the tags in this write-up.

The second line indicates that this document is of the type as specified in the *course_description.dtd* document. The third line asks web-browsers to use the *course_description.xsl* document to render this document. The contents proper is nested inside of the **course_description** element. There, we find information on the course **id**, its **title**, number of **credits**, and a brief catalog course **description**.

```
<?xml version="1.0"?>
<!DOCTYPE course_description SYSTEM "course_description.dtd">
<?xml-stylesheet type="text/xsl" href="course_description.xsl"?>

<course_description>
      <id>
            CSSE100
      </id>

            techniques, and elementary computer programming.
      </description>
</course_description>
```

Figure 1: XML document for a sample course description

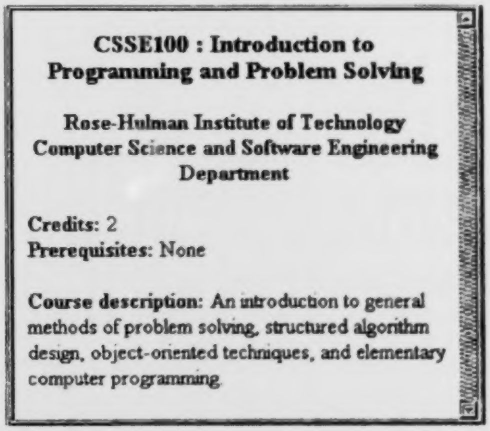
Element names are chosen by the author of the DTD. A web-author has the option of using an existing DTD or to design their own. A key principle of XML is that element names are used to indicate kinds of contents. Notice that there is no formatting information present. This is in contrast to HTML, where tags are used to format contents. This is the primary difference between XML and HTML. We will now explore the ramifications of this difference.

Since in XML, elements are used to indicate kinds of contents, content providers do not have to be concerned about formatting. This of course greatly simplifies the life of the typical academic web-author, who lacks time to memorize HTML formatting tags and who oftentimes spends considerable effort fiddling with HTML tags to obtain a halfway decent looking web-page. While authors who prefer to edit their documents with plain text editors still have to memorize XML elements, we will show in the section on "Ease of Editing" how even this can be circumvented.

In order to render an XML document, XML elements have to be translated into HTML formatting tags. We decided to use XSL over CSS, because of its wider range of transformations. XSL stylesheets are rather complex and can be lengthy. We will not present a stylesheet here, but refer the interest reader to (Wollowski 2002) which contains the stylesheet used to render the XML document from figure 1. The result is displayed in figure 2.

XSL stylesheets are complex. They should be edited by someone familiar with them. Alternatively, it may be advisable for contents providers to adopt a DTD and stylesheet from other organizations rather than editing their own.

There are several benefits to a well-designed stylesheet. (i) If all pages of a given kind reference the same stylesheet, then they all appear the same. This greatly aids users in finding information across courses. (iii) If changes to the appearance of course pages have to be made, only one document has to be edited. (iii) Content providers only have to reference a stylesheet. This leaves the worry over appearance to specialist versed in web-design. Since every HTML based web-page has to be concerned with form in addition to contents, not having to worry about appearance offers a significant time savings.



CSSE100 : Introduction to Programming and Problem Solving

Prerequisites: None

Course description: An introduction to general methods of problem solving, structured algorithm design, object-oriented techniques, and elementary computer programming.

Figure 2: Sample XML document as rendered by our stylesheet

A further benefit of XML is the ability to take information common to documents and place it into a separate file. For example, the document of figure 2 contains information about the department and institution. Notice that they are not part of the file displayed in figure 1. Since this information is common to all course description pages, we placed it into a separate file which is displayed in figure 3.

```
<?xml version="1.0"?>
<!DOCTYPE course_description SYSTEM "course_description.dtd">

<departmental_information>
        <institution>
                Rose-Hulman Institute of Technology
        </institution>
        <department>
                Computer Science and Software Engineering Department
        </department>
        <term>
                Fall
        </term>
        <year>
                2002
        </year>
</departmental_information>
```

Figure 3: XML document containing departmental information

In our experience, one of the most time consuming and menial tasks is the updating of web-pages between terms as this requires changing term specific information. By referencing files with common information, only one (or few) documents have to be changed, with obvious benefits for sanity and consistency.

Notice that the file from figure 3 contains information that is not displayed on the course description page. The additional information is used for syllabi pages.

BEST COPY AVAILABLE

An often overlooked aspect of XML are Document Type Definitions (DTDs). DTDs serve to specify XML documents. As such they can be regarded as specifying classes of XML documents. A contents provider should consult the DTD for the kind of document that they plan to author, in order to learn about the available element names, the order in which they should appear in the document, and whether they are necessary or not. XML documents are currently not validated against their associated DTDs, hence a lot of authors do not create DTDs. However, there is an important reason why one should prepare DTDs. Stylesheets are used to render XML documents. In order to properly render an XML document, the stylesheet should have formatting directives for all elements to be expected in an XML document. The author of a stylesheet should consult the DTD for the type of document they wish to render. As such, a DTD serves as much to document a stylesheet as it serves to document an XML page.

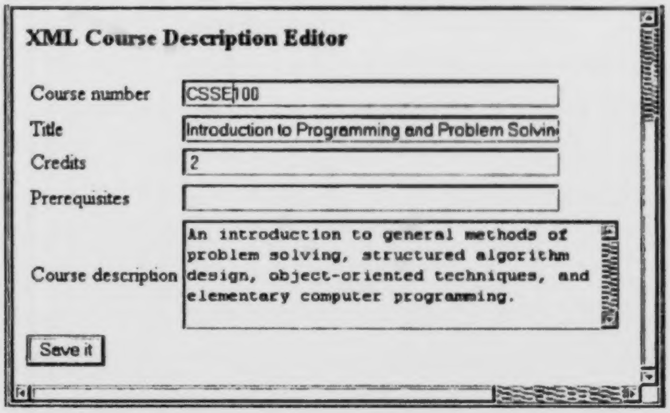
Another important reason for providing DTDs, is that they enable the automatic generation of XML editors, a point that will be revisited in the following section.

Ease of Editing

There are several ways in which content providers may edit XML documents. The most straightforward way is by using a regular text editor. In this case, authors have to memorize element names as well as the structure imposed by the DTD, or they have to have the DTD handy. Due to the semantic nature of the elements, memorizing element names is not too much of a chore.

For web authors who prefer the use of text editors, we provided a template for a sample course document. Naturally, a document of an existing course could be copied, but it may not contain all elements.

For web authors who are not willing to use text editors, we provide a forms based web-page which prompts users for information to be placed into given elements. Figure 4 contains a screenshot of the editor for our course description pages. When using this editor, authors do not have to look up the DTD or memorize element names. We set up the editor so that certain elements come with default information which can either be accepted or edited. An example of such default information is the prefix for course numbers. The editor, which is password protected, can be used to generate new documents or to modify existing documents.



XML Course Description Editor

Course number: CSSE100

Title: Introduction to Programming and Problem Solvin

Credits: 2

Prerequisites:

Course description: An introduction to general methods of problem solving, structured algorithm design, object-oriented techniques, and elementary computer programming.

Figure 4: Interface to editor for course description pages

Since XML documents are only concerned about contents, it is feasible to provide a form field for each XML element. Right now, the fields are hard coded into the editor. We are currently working on ways to automate the editor so that it dynamically generates form fields based on a DTD.

One of the concerns when using XML are last minute additions to a document which fall outside of any given XML element. In general, the contents are rendered. However, there will likely not be any formatting. In order to format such additions, the stylesheet would need to be modified or expanded, with appropriate modifications of the corresponding DTD. This is a very time consuming effort and such

BEST COPY AVAILABLE

changes should probably be made only in consultation with the department. To enable authors to make last minute additions to an XML page, we provide them with the ability to use regular HTML tags.

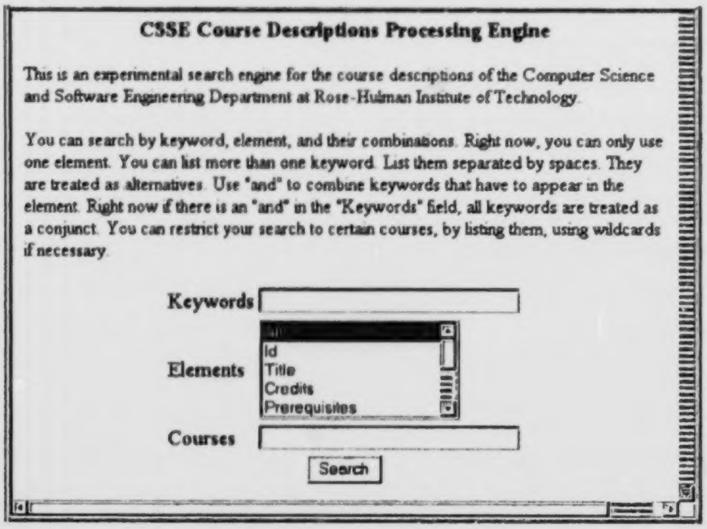
In XML documents, each element must be closed by its corresponding tag. This means that when including HTML tags into an XML document, matching end tags must be present. As such, HTML code has to conform to the original specification of HTML, something that current browsers do not enforce.

If authors follow this simple rule, our stylesheet can render inline HTML code properly. We edited a stylesheet that can render HTML documents, and reference it from the stylesheet for the course description pages. This is another case where XSL shines. With XSL, one can include additional stylesheets into a particular stylesheet.

Another benefit of XSL is that stylesheets can be set up to process missing information. For example, the XML document of figure 1 does not contain information on the prerequisites for that course, yet the web-page from figure 2 states that there are none. This information was purposefully placed there by the stylesheet. Knowing about this ability of a particular stylesheet, web authors can further reduce their work.

Pinpoint Searching

A major benefit of XML is the possibility for vastly improved web-search. Due to the semantic nature of XML elements, search can be restricted to elements, thereby pinpointing searches. XML searching is an acknowledged research problem and we are only beginning to explore the exact benefits of searching XML files. Figure 5 contains a screenshot of the search engine for our course description pages.



CSSE Course Descriptions Processing Engine

This is an experimental search engine for the course descriptions of the Computer Science and Software Engineering Department at Rose-Hulman Institute of Technology.

You can search by keyword, element, and their combinations. Right now, you can only use one element. You can list more than one keyword. List them separated by spaces. They are treated as alternatives. Use "and" to combine keywords that have to appear in the element. Right now if there is an "and" in the "Keywords" field, all keywords are treated as a conjunct. You can restrict your search to certain courses, by listing them, using wildcards if necessary.

Figure 5: Interface to search engine for course description pages

There are a variety of searches that can be performed with it: (i) One can search for one or more keywords inside of one or more selected elements. The keywords can be treated as a conjunct by including the keyword "and" in the search term. Alternatively the keywords are treated as a disjunct. (ii) One can search for keywords in entire documents. (iii) One can browse pages by element, by leaving out keywords. In this latter case, information of the selected element is displayed for each of the documents accessible to the search engine. In the "courses" textbox, one can restrict the search to the documents specified.

The type of search engine made possible by XML is advantageous for many kinds of users. Consider searching the course description pages. If a student has taken a certain course, they can search the prerequisites fields with that course's number to see which other courses they can now take. Prospective students may search course descriptions for reference to certain programming languages.

BEST COPY AVAILABLE

Given information on which courses a students has taken, prospective employers can search syllabi for a whole host of interesting information. For example, they may be interested in the programming languages to which a student was exposed, or the kinds of projects in which they participated, or the kinds of books they were supposed to study. As such, XML is more than a search engine. We like to refer to XML based search engines as *information processing engines.*

Our search engine is custom tailored to the XML document (as specified in the DTD.) Next to the editor, a customized search engine is the second piece of software that can be automatically generated from a DTD. At this point, our search engine is very primitive. There are many open issue that need to be addressed. We are working on some of them.

Multiple formats

The existence of a single stylesheet for documents of a given type ensures a uniform appearance of those documents. However, sometimes instructors prefer a certain appearance over another. For example, some instructors prefer a navigation bar at the top of a web-site, while others prefer to locate it at the left-hand side. While violating the principle of uniformity, those wishes can be adapted by providing stylesheets which implement those ideas. To go one step further, we are currently working on a way to enable students to select the stylesheet that most suits their web-surfing habits.

Conclusions

Using a sample course description, we have shown how to harness the power of XML to provide tools for convenient editing and maintenance of course description pages. Due to the separation of form and contents in XML, it is very natural to obtain a uniform appearance of departmental course pages. Last but not least, we have shown how to easily generate precision search engines, which are useful for current and prospective students as well as prospective employers.

During the presentation we will demonstrate the software for editing and searching syllabi. We will also report on faculty feedback when it comes to editing pages and student feedback in regards to ease of search. At this point, we want to gain more experience with our chosen set-up. In order to be scaleable, further work has to be done on the design of the search engine. We are currently working on this problem and will give a status report at the meeting.

Realistically, XML presents an exciting avenue for those departments that have not moved to courseware products. However, even departments that have adopted courseware products way wish to investigate the benefits of XML technology. The current lack of integration with systems such as Banner does not pose a problem, as course pages are fairly independent of information stored in Banner type systems. In our department, we have several pieces of software aimed at providing some of the functionality provided by courseware sites, giving us the power to tailor them to our needs.

For those interested in learning more about XML, I found the following books very useful (Harold & Means 2001, Williamson 2001).

Factors Limiting the Proliferation of E-learning within Small to Medium Sized Enterprises

Dan Wood, NTP Information Solutions Ltd, Sheffield, United Kingdomdwood@ntp.co.uk

Jason Watson, School of Engineering, The University of Huddersfield, United Kingdom j.a.watson@hud.ac.uk

Abstract: In today's cut-throat economic climate companies have to look more than ever for new ways of operating efficiently. When a company looks for ways of reducing its fixed expenditure it is inevitable that long-term investments, such as the budget allocated for training, will come under scrutiny first. So, as companies become leaner, and budgets become tighter, the money allocated for training becomes tighter. At the same time there is pressure to maintain a well trained workforce and good on-going training programmes are essential to the recruitment of well qualified staff. As a consequence, trainers and managers of companies are looking increasingly towards employing E-learning to fulfill the need for alternatives to more traditional methods of instruction. However, despite the unprecedented success of E-learning technology within big business, the take-up within small to medium sized enterprises (SMEs) has been somewhat less meteoric. This paper explores the factors inhibiting the utilization of E-learning technology by SMEs, and the innovations the E-learning industry has implemented to overcome them. Particular focus is given to the issues surrounding payment for online leaning content. Conclusions include recommendations for future E-learning developments aimed at SMEs.

Introduction

The World Wide Web has provided methods of supplying tailored, measured and assessable learning material throughout the globe in ways which were unimaginable just a few years ago. The Internet has made distance learning a serious alternative to classroom based training. However, the industry uptake of E-learning technology has been somewhat disappointing – although E-learning technologies have a foothold with key market leaders, notable examples being Cisco, Dell and Microsoft, uptake within the small to medium sized enterprises (SME) sector has been slow.

This paper investigates reasons, both environmental and cultural which may be preventing the smooth integration of E-learning technology, and also aims to investigate the technologies which may increase the lacklustre proliferation of E-learning at the lower end of the financial spectrum, focusing on the integration of modern and innovative e-commerce technologies.

The SME Market

According to the European Commission Information Society Directorate-General an SME is a business which employs less than 250 individuals, and has an annual turnover of less than 40 Million ECU or an annual balance sheet total of 27 Million ECU (European Commission 2002). In the USA the definition is slightly different: 'up to 300 employees, total assets of up to $15 million, and total annual sales of up to $15 million' (IFC 2002).

98% of the 3.7 Million businesses trading in the UK are SMEs (by EU definition) (Small Business Service 2000). In the UK; SMEs account for 51.1% of all turnover and employ 55.1% of all those employed.

In Canada; 6 out of 10 employees work for SMEs (Canadian FIB 2002 - Slide 4). The same statistics also state that 58% of all Canadian SMEs prefer an informal approach to staff training, whereas only 33% have a structured training system (Canadian FIB 2002 - Slide 4). Formalised classroom based training is often beyond the financial reach of smaller businesses, and the only realistic cheaper alternative currently available is computer based training (CBT). In the next section, reasons which may account for such a high percentage of SMEs rejecting formalised training are explored.

Factors Inhibiting the Growth of the E-learning Industry in the SME Sector

Legacy Computer/Training Systems

Larger industries have been implementing E-learning solutions for many years, with some significant successes. The focus in many large companies is not the integration of computer based learning CBL into their infrastructure, but rather the amalgamation of many individual, unrelated systems. British Airways have accomplished this, not inconsiderable task with some success. Their 60,000 employees now share a unified training system (Department of Trade and Industry report 2001) which gives all employees access to the same recourses throughout the company. The SME CBL market is not as mature as that of larger businesses, so proper planning of systems as they are integrated should be a consideration to avoid situations such as those prevalent in the E-learning systems of companies such as BA a few years ago.

Utilising modern E-learning software on legacy PCs may pose a major problem for SMEs, in response to this; CD-ROM based CBT is often inherently 'platform specific', that is to say it is designed to run on one specific operating system or type of computer. Many companies now develop content designed to run in any web-browser, on virtually any PC capable of supporting this kind of rudimentary software. As with CD-ROM based applications; there are, however, pitfalls in this approach – in order to deliver interactive learning content incorporating complex multimedia several 'plug-ins' and supplementary applications may be required (for example: Online Expert 2002), for instance 'Flash', 'Real-Player' and 'Acrobat Reader'. Although implementing these multimedia features expands the range and possible interactivity of learning content, implementing them increases the system requirements of the host computer, and makes use of 'thin clients' such as hand-held computers more difficult. An example of a system, which requires the user to install several components in order to function properly, is the system run by 'Online Expert'. This system also requires an up to date version of 'Microsoft Internet Explorer' browser to be installed, further limiting use of the system by those users who do not use Microsoft technology.

Perceived Ineffectuality

One of the major obstacles to the expansion of E-learning techniques into the SME market is the perceived ineffectuality of the learning material. Technology improvements and innovations in the E-learning sector in recent years have led to dramatic increases of the quality and effectiveness of online learning and computer based training; including levels of interactivity and multimedia content which were impossible just a few years ago. Tests have shown however, that negative preconceptions still exist regarding the effectuality of CBL (Dewhurst Et Al 2000). The same research also indicates that most negative preconceptions about CBL are reversed once effective, modern learning content has been sampled. These prejudices do still exist, and overcoming them is one of the greatest limiting factors on the success of E-learning. The level of interactivity and multimedia content of learning material delivered online has scope for even greater improvement due to the enhancements in streaming technologies, and the increased use of 'broad-band' Internet connections. All these innovations should help to convince sceptical SMEs that there will be an acceptable return on investment provided by E-learning systems.

Large training providers tend to deliver their online learning content through a Learning Management System (LMS). An LMS is a control application that facilitates the administration of learners, and the learning material they have access to; allowing a supervisor to track a student's progress through a course. An effective LMS will usually facilitate the measurement of system performance, providing feedback to a company regarding the usage by staff, and assessment results. An LMS can also ensure that trainees have completed the amount of training and achieved the level of skill required to comply with relevant standards.

Computer Anxiety

Within certain industrial sectors, computer anxiety is still a defining factor in the selection of a training methodology. Anxiety can be predicted and pre-empted within the workplace; certain social groups are more prone to suffering excessive fear or mistrust of computer systems. These groups may be predicted from general demographic information (Mikkelsen Et Al, 2002), and although these problems may be overcome with additional training, many companies may see this as unnecessary expense and be unwilling to embrace computer based learning for this reason alone. (Sun HC 2000) CBL needs a prerequisite of computer proficiency to be attained before it can become effective. To an individual who has, for instance, never had cause to use a mouse; beginning a computer course would be impossible without some human teaching intervention. Several training solutions have been instigated to address this; in Europe, ECDL (European Computer Driving License) courses are available from many training vendors. These low cost courses provide an introduction to computing for users with little or no experience with IT systems (ECDL Tutors (2002).

Perceived High Cost

Perceived high cost is one of the prevailing factors which influence the SME market's continuing rejection of E-learning culture; this is a problem particularly prevalent with learning content which is delivered via the World Wide Web. Online delivery of learning content is fine for 'wired' companies with permanent or 'always on' Internet connections, but for many SMEs the Internet is still a seemingly expensive luxury. This problem recedes with every year that passes, as more and more individuals and businesses are connected to the Internet through free services, or services that use a flat fee system, rather than charging 'per-use'. A greater problem is the lack of Internet access for individual employees within SMEs. In the UK this could pose a substantial obstacle to individual usage of online Elearning systems. Corporate paranoia over security breaches and employee misuse of the internet in the UK have led to this situation, improvements in security systems and staff monitoring are slowly remedying it.

The method of purchasing online training materials may be a contributing factor in the continued failure of the E-learning industry to penetrate SME sector. In general, companies wishing to offer their employees online or computer based learning must either design it in-house, commission bespoke software or purchase an 'off the peg' solution from an existing training provider. Generally the cost is the main inhibiting factor regarding systems designed to meet a specific companies' needs. Generalised 'off the peg' solutions are fine for 'general' training needs, but many companies require training on relatively exclusive systems and skills.

One solution to this particular problem is the modularisation of learning content. Several companies offer training solutions involving a process of selection of several modules from their catalogue, ultimately creating a customised learning experience without the added cost of creating whole courses for a specific company or application. This approach can save money by reducing the overall cost of a customised training solution, but may inspire doubts in customers who may feel that they do not receive a training solution truly designed to meet their needs.

Perceived Lack of Structure and Guidance

In the absence of a formal 'teacher', motivation of learners can become a problem. The environment within which learning takes place is an important factor, as the workplace is not usually a location associated with formalised learning, students may find it hard to concentrate. Without a tutor to structure learning, define deadlines and monitor student progress, motivation may be lost. An LMS can incorporate features which can replicate some of the functions of a tutor and is a highly effective way of deploying modularised Elearning content over the World Wide Web (JJ Kuisma & JA Watson 2002), providing a framework for assessment and tracking of individuals learning in ways that even classroom learning cannot match; it is possible to assess, not only what a student reads, but also how fast and at what time.

An extension of modularisation is 'intelligent tutoring' (JJ Kuisma & JA Watson 2002). Basic modularised training consists of a content designer, be that a tutor or student supervisor, creating a learning path, through a series of modules. These separate modules form the 'lessons' in the online course, a students path through these modules is often linear and static. There are several obvious problems with this; students may require further tuition on certain concepts within the subject, but not on others. Because the path through the course is pre-set, a student must seek other means to fulfil his or her learning requirements. Intelligent tutoring offers an effective solution to this problem; the learning path is dynamic; once a student has embarked on a module, his/her path through it is not statically defined. This makes several exciting learning concepts possible; if for instance a module is assessed regularly throughout it's course; for instance once every two 'pages' of learning content, a student's answers will alter the path they take through the learning content. For instance, if the student gets questions on a particular concept incorrect, he/she may be directed through an extra module clarifying the subject (A Patel Et Al 2000).

This system may also provide more challenging systems of 'in-course' assessment, if an end of section test is failed and must be re-taken, an intelligent tutoring system could provide an entirely different set of questions (covering the same subject of course) drawn from a central 'pool' of questions on the module. This way, it would not be possible to simply learn the answers to the questions a student answers incorrectly; actual understanding of the subject matter would be necessary to pass the module.

Commitment/Payment

There are several issues regarding the payment method when purchasing online E-learning material, which smaller companies may find daunting. Many E-learning providers require a large initial outlay; customers often have to purchase entire courses or series of courses at once. Some companies offer more SME friendly systems – whereby smaller modules of learning content are purchased (obviously for a smaller price). However, these systems usually require a commitment of a large 'initial set-up' fee or, at best; an account with the training company. This kind of commitment requires great confidence in return on investment, E-learning concepts and the companies providing them. This confidence is often not forthcoming in SMEs.

One method of payment for E-learning content focussing on recognised qualifications is to create a system whereby the 'lessons' are free, but the assessment required to obtain the qualification is chargeable. Thus SMEs may sample the learning content, without any obligation, but once the training is completed may decide to purchase the accredited qualification.

A LMS may also provide a mechanism for 'pay-per-use' charging of learning content. The problems outlined above, regarding the purchase of learning content can be made even more complicated with the introduction of non-linear learning paths (as in intelligent tutoring systems). The LMS can sidestep most of these payment problems relatively easily – the LMS may track all actions a student takes while moving through a course. This information could not only be used for monitoring of an individuals learning, but also their chargeable usage of the system. Some companies are beginning to utilise pay-per-use systems such as these, but the concept is still, largely speaking, in its infancy. In general, companies still require registration of an account to access and use learning content; this is a handicap when dealing with small companies for which this system may represent a daunting commitment.

In order for a pay-per-use system such as the one described above to be truly effective, a commitment free way of transferring relatively small amounts of money would have to be implemented. Unfortunately credit cards are not suitable for this purpose. Since the introduction of 'Diner's Club' (the world's first universal credit card) in 1951, the credit card transaction model has remained largely unchanged. The general model of an online credit-card transaction is very similar. Generally a customer locates the products he/she wishes to purchase and places an order, supplying a credit card number and various personal details for verification. Once the merchant receives the order, it contacts the credit card issuer to verify the customer is authorised to remove the funds. In order to complete a transaction, the following information is supplied by the merchant: Merchant ID, Valid card number, Expiration date, Credit-card limit and Card usage. Either; the transaction is refused, in which case the customer is informed and the sale is cancelled, or the transaction is approved, the funds are transferred electronically to the merchant and the goods are dispatched to the customer (Lamond 1996).

The main flaw with credit card transactions is cost. Mainly thanks to the increase of fraud, online and otherwise, coupled with the administrative tasks required to perform a credit card transaction, the effective 'cost' to a merchant has increased. The money required recovering stolen or misplaced funds, and the lost funds themselves contribute to this overhead. This situation effectively means that it is only economically practical to make credit cards transactions above a certain monetary amount. In the offline world this is not a major problem. Smaller purchases (of a few pounds or a matter of pence), i.e. a bus ticket or a newspaper, can easily be purchased with cash. However, because of the overhead on credit and debit cards it is currently impractical to purchase items such as these remotely through the Internet or over the phone.

Generally, e-commerce websites are centred on the sale of items and services of a value of at least £10.00 (GBP). Although websites do sell items below this price, they usually do so alongside more expensive products, rarely does a seller specialise in extremely small goods. The monopolisation of the online shopping community by credit card based payment systems has proved to be the stumbling block to the sale of small scale intellectual property e.g. online newspapers, sports scores or in this case; E-learning material. To attempt to facilitate the purchase of low value items, several systems have been devised. Unfortunately, mainly due to poor industry collaboration and low retailer uptake, the systems have not been adopted widely by consumers and consequently many have failed.

Many recent notable systems have relied on a subscription based approach to the purchase of goods. A user purchases 'electronic cash' via credit card, in a large enough denomination to make a credit card purchase financially viable e.g. £15.00, then uses this electronic cash in much smaller units to make purchases at participating vendors. The accepted terminology for such small purchases is Micropayment (M Liskov 2001). In principal this model is a viable method of making Micropayments remotely or online. A similar system to the one described above was implemented by Digicash. The system was developed by the renowned Dr. David Chaum and, in its infancy, was billed as the future of electronic payment systems. Unfortunately Digicash filed for bankruptcy in 1998, and in early 1999 was acquired by eCash Solutions, who discontinued the project (McCullagh 2002). One flaw of this product, which may discourage a merchant from taking it up, is the requirement of subscription and initial deposit. This removes the possibility of 'impulse buying' for non-subscribed users. Also, consumers may be unwilling to deposit relatively large amounts of cash with a company who may only have one or two merchant partners. Effectively a customer could be left with an 'e-wallet' full of 'e-cash' and nowhere to spend it.

This unwillingness to support new and un-established services by both consumers, and the retail industry as a whole has brought about the birth of many innovative methods of utilising existing Micropayment systems. For example, telephone users are effectively already equipped with a fully functional Micropayment system: Calls costing a small amount are paid for as part of larger bill, at a regular interval. The Orange network has already implemented a mobile telephone based Micropayment system in Denmark, with promising results. This could be extended to an E-learning system, for instance by utilising the chargeable Short Message Service (SMS) (used to purchase mobile telephone 'ringtones' and graphics by hundreds of vendors in the UK alone) to pay for learning content as and when it is required.

Purely online payment systems have also attracted the attention of some major IT companies in the last couple of years: most notably Millicent. This is a Micropayment system implemented by Digital Equipment Corp, now owned by Compaq. The system went live in June 1999 in Japan, with wallets starting at 1000 yen and payments as small as 5 yen (approximately £0.025 at launch time). The system was also given a trial in the USA. Compaq claim MilliCent's trial run went "extremely well." The trial had 10,000 users buying small pieces of content from more than 45 vendors, including the Oxford University Press, which sold dictionary lookups; and the University of California at Berkeley, which sold individual book chapters (Mitchell 1998). About 84 percent of the transactions were for less than 25 cents, and 73 percent were for less than 5 cents. The median transaction was for 2 cents, but, thanks to a few people who spent a few dollars at a time, the mean average was 30 cents (Mitchell 1998). Despite these early promising reports, development of the system is currently suspended indefinitely (Compaq 2002). Compaq spokesmen claim that this is due to the company's focused nature, and a desire to remain largely in the business of the supply of hi-tech hardware. Compaq are planning to license the software to a third party to complete the development (Mitchell 1998).

Conclusions

Uptake of Elearning by SMEs has been slow and this is mainly due to the cost efficiency of an E-learning solution being tied to economies of scale. SMEs have fewer staff and less money to spend on training than larger companies and often find paying for the development of a bespoke E-learning solution too expensive to swallow. The E-learning industry is responding to this by developing generic products aimed at specific SME markets. However, these products are still perceived as expensive at the point of sale. In addition, the generic content of such material does not always match a SME that may have more specific requirements. One solution to this problem may be to examine pay-per-view as a payment option that would make the pill of training expenditure a little easier to swallow.

Commitment free pay-per-view online payment for E-learning content is still in its infancy. Until a form of E-Cash is devised which is globally accepted and achieves a reasonable level of consumer uptake – the truly 'no strings attached' approach to Elearning payment may not be viable. When a suitable system is finally developed, E-learning will become a much more financially viable option for SMEs and the general public, revolutionising the industry in the same way that 'pay-as-you-go' technology did for the mobile telephone industry in the UK. For now, account based 'pay-per-use' LMS based systems may yet provide a convenient and useable interim solution.

In addition to overcoming the financial hurdle of implementing an Elearning solution companies, SMEs especially, need to measure their return on investment. Many of the quality issues to do with E-learning may be overcome with the deployment of an advanced LMS. Several companies already offer Learning Management Systems, of varying levels of depth and effectiveness, and as these systems become more prevalent and standardised they could hold the key to the SME friendly E-learning systems of the future. The measuring and monitoring features incorporated within LMS' should also help to inspire confidence with respect to motivation of learners.

ABSTRACT

While electronic learning environments provide exciting possibilities for supporting learners, the design of the user-interface is as yet little understood. The purpose of this paper is to investigate the importance of specific usability attributes for on-line learning courses. To realize this authors first content the need for designing learner-centered interfaces. A review of related papers on usability methods used and learning theories is presented. The results of a usability study evaluating the use of a Virtual Learning Environment providing Distance Learning for Post-Graduate studies in three Greek Universities using WebCT, a well-known elearning delivery platform, are presented. Finally, the review and the results of the study point towards specific usability attributes that need to be considered while designing usable learner-centered interfaces.

Keywords

On-line learning course, usability, learning theories, learner-centered interface, usability techniques, usability attributes.

1. INTRODUCTION

As information and communications technologies become more and more pervasive, expectations for educational computing are becoming greater and greater. Advances in electronic and web-based technologies offer online learning courses for learners (either students in educational settings or young professionals in organizational contexts) the opportunity to become skillful and acquire knowledge. There is an expectation that these technological advancements will make education and training available to a much wider audience of learners with diverse backgrounds and ages.

Given the importance of online educational computing for learning, *the need for evaluation of these technologies* becomes crucial (Jones et al., 1999). Squires (1999) points out clearly the need for *integration of usability and learning* as "*workers in HCI and educational computing areas rarely speak to each other or take note of each others' work: the educational computing literature is littered with naive and simplistic interpretations of interface design issues, and many writers in the HCI literature appear to be unaware of the significant developments that have been made in theories of learning*". Squires and Preece (1999) further argue that scholars have not considered the implications of usability features of an educational package in order to achieve educational goals: being educationally *beneficial*. Along the same vein Cronje (2001) asserts that "*although learning on the Internet is becoming more and more usual, it would seem that most of it still takes the form of virtual lectures*".

It is important in such environments to understand how usability contributes (or not) to educational goals (Jones et al., 1999). To this end, this paper argues that there is a need for usability scholars to consider the way in which usability and learning (special emphasis on user interfaces of on-line learning courses), interact. It is therefore, the aim of this paper to examine specific usability attributes that need to be considered.

To address this issue the paper is divided into 3 sections.

2. THE IMPORTANCE OF USABILITY FOR ON-LINE LEARNING COURSESS

The authors content that while designing on-line learning courses one needs to consider the usability of a web user interface. In this paper it is argued that usability of an on-line course's user interface can significantly affect learning.

In order to address the issue of usability one needs first to define the context of use of an on-line course. Increase in the diversity of learners, technological advancements and radical changes in learning tasks (learner interaction with a learning/training environment is often an one-time event); present significant challenges and render the possibility of defining the context of use of online learning courses. It is of great importance to point out that unlike users of a traditional software product return time and again and gradually learn the interface, the instructional interface must make sense quickly since the user is unlikely to use the environment for an extended period of time.

Thus a good starting point would be to pose the following questions: What is the role of usability in the context of modern educational software design? Which usability attributes affect on-line learning?

To answer the first question these authors provide a review of learning theories and usability techniques and how these are used to improve the user interface of on-line learning courses. The results of this review will be used to conduct a usability study aiming at identifying usability attributes that affect users in on-line learning, thus answering the second question.

2.1 Applying Learning Theories

Chalmers (2000) links learning theories as well as instructional theories in order to present potential user interface improvements for research and development of computer-assisted instruction interfaces. This author suggests allowing quantification of observable results into the screen, use table of contents and the ability to link a chapter with the other chapter can be applications of behaviorism and cognitive learning theory respectively that can lead to learning.

Norman and Spohrer (1996) combine constructivism and problem-based learning with learner-centered approach: places the learner at the center of the interface design. Using constructivism theory learners are motivated to seek out new knowledge when they confront real problems at hand. The goal is active exploration, construction and learning and not the passivity of the lecture attendance and textbook reading. Norman and Spohrer (1996) assert that while this philosophy is not new the current applications are. The ideas of active exploration and construction of meaning as well as the motivation to solve real problems in authentic contexts are here for ages. These authors focus their analysis on three dimensions of instruction: engagement, effectiveness and viability. Engagement is tightly associated with motivation and the provision of rapid compelling interaction and feedback help make learners motivated and engaged. Effectiveness is a major concern because after all, learning as such is the most critical issue. Viability includes the issue of scalability, the technological infrastructure (authoring tools, design tools, component software standards etc) as well as the social and cultural one (integration into existing learning/training activities etc).

While learning theories can be applied to design on-line courses still the question remains (Dringus, 1995b): How does an instructor know that the course interface provides full potential for students to access and utilize the information that is being presented? Evaluations of online learning courses should include learners' perceptions about the course interface as well.

Application of learning theories onto the design of online learning courses' user interfaces cannot give answers to usability scholars. In fact Chalmers (2000) stresses we neither know *"...if we can generalize learning theories from the classroom to the computer lab"* nor *"...if we can generalize instructional theories from the text to a software tutorial"*. Further research needs to be conducted before these conclusions can be drawn.

Systematic evaluation of the efficacy of various media integrations and the usability of the interface and its functional components is missing. To this end, the next section reviews current usability evaluation techniques as they have been applied on on-line learning courses.

2.2 Applying Usability Evaluation Techniques

Parlangeli et al. (1999) conducted three studies: a heuristic evaluation, a usability test, learning assessment; regarding the evaluation of the multimedia course. The results of the usability test (using ten people) revealed many usability problems similar to those identified by the heuristic evaluation. The perceived low-level usability resulted by both studies have had a common denominator: scantly usable hypertextual structure. Additionally Parlangeli et al. conducted a third study focused on learning assessment. To evaluate the effects of learning using the multimedia course, given that this course evaluated as a poorly usable system, the learning performance of three homogeneous groups of students performing the same tasks although working with different tools was considered. These tools (a CD, a book and printed materials of the CD) were allotted to each student group. When the learning phase was completed, the students were given a multiple-choice test to assess their performance. There was no significant difference in the learning performance among the three groups of students.

Evaluating learning may move usability practitioners outside their comfort zone. In order for usability evaluation techniques to be more effective, they need to familiarize themselves with the evaluation frameworks and methods from instructional design (Lohr, 2000). Also essential are acquaintance with educational testing research (Rovai, 2000), learning styles (Terrell and Dringus 2000; Kolb 1984), and the rudiments of learning theory (Lin and Hsieh, 2001).

Web design heuristics that have grown up around e-commerce can also be used to evaluate online learning courses. Dringus (1995b) proposes that usability heuristics suggested by Shneiderman (1987) and Nielsen (1993) can be applied to evaluate on-line course interfaces. However, these heuristics should be used with caution since many assumptions about the users of e-commerce do not apply to on-line learners. The challenge for most types of on-line learning is that established sets of heuristics do not exist. Pedagogical guidelines typically have to be developed that will be combined with the aforementioned heuristics.

Towards this direction Squires and Preece (1999) realized that simple application of these heuristics could not be effective because they fail to address the specific challenges of learner centered interface design as well as the issue of integration of usability and learning. Thus, these authors proposed an adaptation of Nielsen's (1993) heuristics, taking into account socio-constructivism tenets (Phillips, 1995; Soloway et al., 1996). The proposed set of "learning with software" heuristics contains the following:

- Match between designer and learner models
- Navigational fidelity
- Appropriate levels of learner control
- Prevention of peripheral cognitive errors
- Understandable and meaningful symbolic representations
- Support personally significant approaches to learning
- Strategies for cognitive error recognition, diagnosis and recovery
- Match with the curriculum

These authors do not claim that this is a final set of heuristics. Rather it is an initial attempt towards integration of usability and learning that needs further discussion and elaboration.

Finally, established sets of principles of what works for on-line learning, based on research findings or industry best practices, do not yet exist. The usability standards and tests that have proven their worthiness for e-commerce and other applications need to be transformed before being applied to on-line learning tools and applications. However, some preliminary attempts towards this direction have been made and will be further discussed.

Relevant to *navigational fidelity* is the work conducted by Parlangeli et al. (1999). The working hypothesis was that the level of usability of an online course could affect the learning performance. The results indicated that students' knowledge related to the content of the course under evaluation was not higher after the use of the system. More specifically, students provided low ratings to the navigation of the multimedia course. Parlangeli et al. (1999) concluded that the complex structure of the multimedia course indeed affected students' performance.

Addressing the heuristic of *understandable and meaningful symbolic representations* Cronje (2000) investigated the issue of "what extent can some of the methods used by educators be replicated over the internet". To this end this author poses the question: How do adult learners respond to internet-based role-play exercises and youthful methaphors? The challenge was to design a virtual learning environment by using metaphors applying theoretical foundations of constructivism. The results revealed that using metaphors can lead to successful and motivational learning and physical attributes of a classroom can be metaphorically recreated in cyberspace.

Terrell and Dringus (1998) focus their interest on awareness, which is "a combination of visual and conceptual cues given to the learner that increases a learner's immediate sense of presence of others in an online class". While investigating the question of "how awareness can be effectively conveyed online" they propose that awareness metaphors can be conveyed in a number of several ways: number of learners and their locations, CVs, online tours, syllabi and readings, study hall, orientation room, research labs, help center etc.

Learning styles issue is a crucial factor while *supporting personally significant approaches to learning*. Terrell and Dringus (2000) investigated the effect of learning styles on student success in an online learning environment. Kolb's learning theory was the basic theory and the Learning Style Inventory (LSI) the main instrument for assessing the learning styles of the participants in the experiment. The results indicated that students that fit with *Accommodator* learning style dropped from the online program at higher rates.

Checklists

The use of checklists date back to the early days of educational software. Squires and Preece (1999) reported several problems evaluators have found with the use of checklists as predictive evaluation tools. Some of them deal with the focus on technical rather than educational issues. McDougall and Squires (1995) content that these problems are symptomatic of the failure to adopt a situated perspective on the use of educational software. Several attempts have been made to provide a more holistic approach of the use of educational software but they resulted in very extensive checklists, which are tedious to apply (Squires and Preece, 1999). Additionally, an analysis of two well-known checklists (one developed by the National Council for

Educational Technology for evaluating CD-ROMs and the American Microsift Evaluators Guide) reveals the lack of attention to usability and the lack of integration between the two issues (Jones et al., 1999).

2.3 Summary

Despite the efforts of scholars from educational research streams and usability the problem still remains. Dringus (1995b) proposes heuristics without further adaptation to the context of learning environments. Squires and Preece (1999) propose such an adaptation but there is a clear need for further elaboration and empirical validation. Parlangeli et al. (1999), conduct their studies by using usability evaluation methods (Nielsen's heuristics, User evaluation of Interactive Computers System Questionnaire) that were developed to address the needs of a user as a computer user and not as a learner. Notess (2001) stresses that the afore-mentioned methods need additional consideration under the light of on-line learning courses and learning environments.

It can be concluded that educational computing literature seems to deploy naïve and simplistic interpretations of interface design issues. An instructional interface comprises of elements that assist the learner in the task of learning. Online courses and other online learning applications, tools and technologies have to be usable.

Under the auspices of SIG, CHI (2001) it has been reported that: (a) very little quality control and usability testing has been going into the designing of courses and the design of e-learning technologies, typically due to time constraints and low perceived importance of usability, (b) there is a need to focus on how to develop useful and usable tools and environments since so far we are focused more on the technology and not on the pedagogy, and (c) there is very little thought at the decision-making level to usability issues.

The review of learning theories and usability techniques provided evidence regarding the importance of usability while designing online courses. The aim of the next section is to identity which usability attributes affect on-line learning.

3. LEARNERS' REACTIONS TO AN ONLINE COURSE

In order to better understand the users' reaction towards web-based learning a study was carried out. This study relies upon a funded[1] project called "XEXO". This is an abbreviation in Greek, which means a space for Education and Training with no limits. The main objective of the project was to develop a virtual space for lifelong learning. This space is targeted to professionals; even post graduate students who seek additional educational and training opportunities.

3.1 Objectives of the study

One of the objectives of this study was to generate users' reactions while using an online learning course that provides Distance Learning. This course supported three Post-Graduate Masters in three Greek Universities: Athens University of Economics and Business, Technical University of Crete and University of Macedonia. To meet students' needs a Virtual Classroom environment was developed using a well-known e-learning delivery platform, WebCT, and computer based tools.

3.2 Implementation of the Web-based Course

The web-based course comprised of six major topics: Knowledge Management, E-Commerce, Activity Based Costing, Business Process Modeling, Statistical Process Control, and Total Quality Management Each university developed two topics. This integrated web-based course was titled *Organizational Transformation* and was equivalent to 42-hour traditional university graduate-level course. The course aimed at developing students' understanding of the emerging issues concerning the aforementioned topics.

A Virtual Learning Environment (VLE) was developed to support the course using WebCT's Computer Mediated Communication (CMC) and World Wide Web (WWW) Tools. The web-based course ran for 12 weeks. The whole learning environment and the learning content were developed in English. The users were full-time students having English as a second language. Each university assigned one tutor for the scientific coordination and guidance of the course and one administrator for the technical and administrative issues.

Lecture notes and slides were pre-prepared, edited and uploaded into the WebCT environment. Lecture notes were developed as plain text with hyper-links (HTML files). Slides were downloadable as Power Point presentations. Students were supposed to preview the on-line educational material and initiate discussions and questions regarding the course if they felt it was appropriate. Associated information on schedule, assignments, exercises and group-work was also available on-line.

3.3 Questionnaire Design

A questionnaire was designed to collect data regarding users' reactions while using the on-line course. In order to design the questionnaire the results of the literature review presented earlier were used.

---

[1] See acknowledgement

The questionnaire consisted of three parts. The first part dealt with demographics questions. The questions related to the user's frequency of use of PC, the Internet, and the e-mail. The second part dealt with the users perception regarding the use of the system. The questions related to the usability of the online course. The user was supposed to answer regarding the importance of each specific usability item using a scale from "1" being least important to "5" being most important.

3.4 Results

It is not the aim of this paper to report all the results of this study. Attention will be paid to the usability attributes that the users rated as highly important while using an online course. To aid the reader the results of the study are divided in three sections: three sections of the questionnaire.

Users Familiarity with the Technology

The results have shown us that the vast majority of students who participated in the experiment were familiar with the use of PCs, Internet and the use of email while they are not really familiar with the use of collaborative tools and most of them prefer the natural, face-to-face way of communication (Table 1).

Use of PC and Internet	
Use of PC on a daily basis	85.37%
Use of PC Few times a week	12.20%
Use of Internet regularly	85.37%
Use of Internet rarely	14.63%
Type of communication methods preferred	
Face-to-face	73.17%
Telephone	17.07%
E-mail	9.76%

Table 1: Familiarity with the Technology

Questions referring to web-based courses' usability

Participants were asked to evaluate the importance of usability attributes of the user interface of an online course. To aid the reader specific usability attributes were enlisted while there was space for free-form comments as well. The results in Figure 1 present the frequencies that the usability attribute was rated as "1" that being most important. It can be derived from the results depicted in Figure 1 that the majority of the respondents were satisfied from the material and variety of content provided. Almost half of them think that navigational fidelity is important. Most of the participants were satisfied with the environment: WebCT. Students felt that they receive good directions allowing them to find their way in the web site. This is obvious since navigation through the web pages of the course is rated as the most important requirement for an online learning course. In terms of activities the students require in order to better attend their distant course they consider the ease of use of the system and the capacity to directly communicate with their instructor as the most important factors.

Free-form comments

Students were asked to propose usability attributes that they consider as significantly useful in a web-based course.

Functionalities	**Frequency**
On-line help and learning performance evaluation	39.47%
Support the use of multimedia files	23.68%
Accessibility	15.79%
Enhancing awareness	10.53%
Efficient searching facility	10.53%

Table 2: Users' Comments

The authors reviewed their answers searching for key words. The results reveal the importance of five additional usability attributes: Support the use of more multimedia files, on-line help and learning performance evaluation, accessibility, enhancing awareness and efficient searching facility (Table 2).

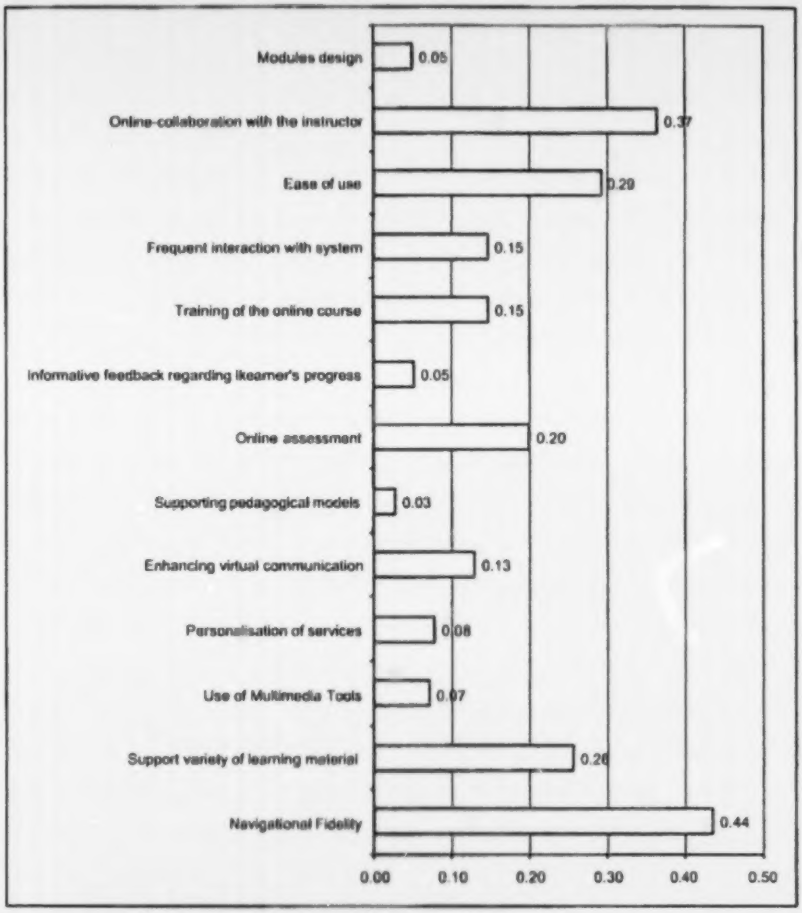

Figure 1: Most important usability attributes

4. CONCLUSIONS

Technological progress allows for further flexibility and power and places the learner in the center of the learning process (Lohr, 2000). In this paper it is argued that designing the interface between a learning environment and the learner is an increasingly critical part of the development of online courses.

First a literature review was presented. The results of the review point towards the direction that scholars currently address the needs of the software environment rather than learning environment where the user and the task are fundamentally different. Current usability techniques as well as learning theories should consider different usability attributes while designing online courses. Learners use these environments to build their expertise. Their interactions with the on-line learning environments may not produce visible results.

Based on these observations this paper examined specific usability attributes that are important to the users while designing online learning courses. To address this issue the results of an experimental study were presented. The results pointed towards five additional usability attributes that need to be addressed by usability researchers and practitioners.

The authors do not mean to say that only these usability attributes should be considered. The results of this study simply provides some light to the continuous efforts towards integrating usability and learning. Understanding which usability attributes should be considered by the designer is an important step towards this integration.

Finally, while there is an abundance of online courses currently available (e.g. Cronje, 2001) still they have not addressed which specific usability attributes an online course should have. Furthermore, the outcome of the learning experience is often not reflected in the interface but on the learner's mind (Lohr, 2000). To this end this paper presented the results of an ongoing effort towards investigating and understanding specific usability attributes that reside on the learner's mind and how these can be communicated to the designer.

ACKNOWLEDGMENTS

The European Commission and the Greek General Secretariat of Research and Technology have funded this work. The authors wish to acknowledge these bodies for their support. The authors would also wish to acknowledge: Prof. Vassilis Moustakis from Technical University of Crete, as a scientific coordinator of the project, Prof. Konstantinos Tarabanis, as a scientific coordinator from University of Macedonia, and Kyriaki Fytraki and Thanasis Giouvanakis as technical administrators from Technical University of Crete and University of Macedonia respectively.

Introduction

The World Wide Web has evolved from a primary text based medium into an integrated net of media. With this change comes the responsibility of the author to ensure that all aspects of the communication on their site are accessible. This communication whether by video, audio, or animation, in its ability to relay information to the audience, is something that should not be discriminate in its delivery.

With the Internet taking a dominant role in corporate training, education, retail, and customer based product exploration; all have to ensure that the media they do deliver is accessible to the widest audience. The technologies capability to enhance, promote, and engage the customer or the learning experience, contributes to the success of the author's intended message. The audience includes those with disabilities.

Whether users have a visual, auditory, physical, or developmental disability, accessible multimedia can enhance and promote the message delivery through the chosen medium. Current Web multimedia technologies of use on the Internet are enhanced and made accessible with some simple modifications and alterations. This paper outlines some of the multimedia technologies currently available on the Web and the means to make them more accessible.

Web Audio and Video Captioning

Captioning is synchronized text that is used as an alternative format to deliver audio content (WGBH, 1992). The goal for multimedia authors should be to provide captions for all audio, including that contained in video and animations. Typically, captions are displayed through a client-side media player.

Designed by the WGBH Educational Foundation in Boston, a public broadcasting company, captioning was originally designed for people who are deaf or hard of hearing (Microsoft, 2002). Like other enabling technologies, captioning and its ability to relay information, can now be seen as an asset to those without hearing difficulties. It's applications for those wanting to learn a second language, learning to read, communication in noisy environments, and people using equipment with poor audio quality, showcases the delivery formats wide application base (Microsoft, 2002). This application base can now be delivered on the Web.

The ability to transfer this alternative audio format for Web based audio and video allows everyone the ability to learn and accept the message of the page author. Through the work of the World Wide Web Consortium (W3C) Synchronized Multimedia Integration Language (SMIL) and various media player contributors, captioning on the Web is a reality (W3C, 1998).

Captioning audio and video in Realmedia. Incorporating closed and open captioning in real player is achieved in several ways. Real Networks, being one of the first organizations to capitalize on the benefits and potential of SMIL and XML, has created their own subset language called RealText (RealNetworks, 2000). RealText is a mark-up language similar to HTML and can be programmed using any standard text editor. This language, which is fully supported through the Realmedia player, allows multimedia developers to incorporate synchronized text, audio, and video without taking away user control. Since the text caption is a separate file within the media presentation, the captioning can be turned on an off by the users and is readily edited.

Captioning audio and video in Windows Media format. Not unlike Real Networks Real media, Microsoft's Windows media will also support SMIL functionality. Through their own XML subset language called SAMI, which stands for Synchronized Accessible Multimedia Interchange, Windows Media player and Encarta products can interpret and playback captions in up to 8 different languages (Microsoft, 2001). SAMI is written in a plain text editor and saved in the same directory as the Windows Media file. Through the Windows Media player closed captions can be turned on an off by the users and edited easily apart from the other media files.

Captioning audio and video in QuickTime. Apple's QuickTime player also supports captioning through the use of QuickTime Text. QuickTime Text is a simple tag-based syntax that reads in text captions and synchronizes them to an audio or video file (Apple, 2002). The text is then imported as a separate track embedded in the QuickTime movie. Closed captioning can be enabled and disabled by turning text tracks on or off, or by incorporating interactive QuickTime elements through software such as Livestage (Totally Hip, 2002) or SimpleCaption (Baird, 2002).

The authoring tools that are available to caption these media elements can be as simplistic as a simple text editor to the multifaceted functionality of Livestage. One tool that allows the author to caption video and audio and save the caption text file in all supported above formats, namely SMIL, SAMI, and QuickTime Text, is MAGpie. MAGpie, or the Media Access Generator, which was created by the National Center for Accessible Media (NCAM), allows authors to create captions for Web based audio and video (NCAM, 1996). This tool is free and available for Macintosh and Windows based computers.

Macromedia Flash

Flash is one of the fastest growing Web media formats. It's ability to supply small file sizes, interactivity, and its scalability has made it a very attractive media element to incorporate into a Website. The problem with this media format, like other Web browser plug-in formats, is that they are not readily accessible to assistive technology. The interactive elements, text and animations that are contained in the media leave the user unable to navigate or access the information within. These problems, however, have been addressed as an add-on extension for Flash 5 and in Flash MX (Macromedia, 2002).

With Flash MX and the Flash 6 Web browser plug-in, developers can now add descriptive text to Flash based animations, forms, movies, and content that is readily accessible to operating system and application-based screen readers (Macromedia, 2002). Macromedia's support for accessibility also extends through the use of the Microsoft Active Accessibility Application Programming Interface (API), which enables the software program to expose information about their content and user interface to assertive technologies (Macromedia, 2002). This is utilized by the application and it's Web plug-in. Some of the specific accessible elements that are incorporated into Flash are (Macromedia, 2002):

- Text based descriptions of Flash elements, which can be read by a screen reader application for those with visual impairments.
- Scalable vector text and graphics, which can be magnified without a loss of quality, for those with visual and auditory impairments.
- Content controls that allow the user to control the playback of content
- Customized colour control for those with colour blindness.
- The ability to synchronize audio with visual elements.
- Mouse free navigation controls
- An Accessibility window in Flash MX to help in accessible Flash creation.

The ability to provide accessible Flash content can also be utilized in previous versions of Flash through the use of the Flash 6 browser plug-in. These older versions of the technology enable the author to utilize long description tags, alt tags, and alternative text for the published movie as long as the audience is using an appropriate screen readers that support Flash (Clark, 2002).

PowerPoint for the Web

Using presentation media presents a challenge to users who are blind, deaf or hard of hearing. More often than not the audio is unusable or the presentation itself is not readable by screen readers (WebAIM, 2002B). There are several techniques that can be used to assist these users in accessing the meaning of media content. These techniques mainly involve creating text equivalents for the graphical data and also creating accessible HTML versions. The four techniques below can all be used to render PowerPoint information accessible to those with disabilities.

Provide the Source File. Probably the best and easiest way for you to ensure that your presentation can be viewed is to provide the users with the source file or the actual PowerPoint file (WebAIM, 2002A). Microsoft has improved its accessibility options within Office 2000 and Office XP and information within the documents outline and description text can be accessed with Office compliant assistive technology.

Saving the Outline Only. You can also save the outline of your PowerPoint presentation as text or rich text and convert that outline to Accessible HTML. With this method you don't get the added benefit of visuals - so if visuals are important to your presentation then you may not want to use this technique (WebAIM, 2002A).

Using the Save as Accessible Plug in. This Power Point Point Accessibility Wizard, which is available free from the Division of Rehabilitation Education Services at University of Illinois, simplifies the task of converting PowerPoint presentations to pure HTML through an easy- to-use user interface (Gunderson, 2002). This plug in converts Power Point Presentations to an HTML format that includes required accessibility information including ALT tags and accessible formatting. Although this tool is still in BETA form it one of the easiest tools to use to make PowerPoint presentations accessible (WEBAIM, 2002A).

Convert Presentations to Video Format. Creating accessible presentation media using Windows Media, QuickTime or Real Media involves captioning or adding audio descriptions. Those with disabilities can then access this extra information contained within the presentation. Conversion of PowerPoint to any of the aforementioned video formats can be accomplished with a variety of tools. Some of the tools available include Real Presenter for Real Media, Microsoft Producer for Windows Media, and QuickTime Pro. Captioning these presentations can then be accomplished using MAGPie (NCAM, 2002), Hi-Caption (HiSoftware, 2002), SAMI (Microsoft, 2002), SMIL (W3C, 1998), RealText (RealNetworks, 2000) or QuickTime Text (Apple, 2002).

Scalable Vector Graphics (SVG)

SVG is an XML (Extensible Mark-up Language) based language that allows images, text and vector graphics to be programmed directly into the Web interface (W3C, 2002). This language allows for the description of two-dimensional objects that can be scaled and manipulated with no loss in resolution of the object. With it's ability to be incorporated directly into the XML coding of the page text equivalents for images, and other descriptive features in the media can be accessed by those who use assistive technologies (W3C, 2002).

Other attributes of this graphics format language is its ability for interactivity, data driven content, and alternative delivery modes and structures for content. This includes directory structures for image equivalents and language alternatives (Adobe, 2002).

Portable Document Format (PDF)

Adobe Portable Document Format (PDF) has become a standard protocol for the distribution of electronic documents via the Web. It's ability to retain the original source documents formatting, fonts, colors, and graphics, regardless of what application platform it was created on, outlines its power on the Web (Adobe, 2002). With the introduction of Acrobat 5.0 and the updated Acrobat reader plug-in, Adobe has included accessibility enhancements to the Portable Document format (PDF) making a very viable option for the distribution of accessible information. With the ability to add tagged information to PDF documents, screen readers can now access PDF text content, logical document structure, and alternative text information for images and graphics (Adobe, 2002). These enhancements allow the reader to follow the intended document organization and reading order while navigating the document.

With accessible PDF documents users can now:

- Follow the logical reading order of the document. This is achieved by defining the structure of the document by using tiles, chapters, headings, and multicoloured text.
- Provide alternative text descriptions for images
- Navigate with embedded links
- Specify document languages to benefit screen readers that may be able to change languages the fly.
- Use windows based screen readers to read the text
- Use keyboard navigation.
- View documents in high contrast mode.
- Zoom in on text and reflow to fit any size view when working with tagged (accessible) Adobe PDF files.

Conclusion

With the use of any Web based information the author is ultimately responsible to ensure that the message is accessible. This includes information that is contained within multimedia. Although these media do possess barriers to those with disabilities through their delivery, alternative delivery methods can ensure that the widest audience receives the message. Various methods, tools and protocols that are currently available, and others in development, can facilitate the creation of these media. These tools however, can only be utilized by those whom are aware of accessibility issues. Through the conscience effort of all that contribute to the World Wide Web, all information can be made accessible.

Panels

E Learning: A Study of Three Types of Electronic Learning Environments

Overview

This panel discussion will consist of a detailed review of three dynamic electronic learning projects of national scope. They are: 1) The National Global Learning Consortium; 2) The National Borderlink Challenge Initiative; and 3) The American Association of University Women Learning Online Initiative.

Importance to the Field

The panel will present information that provides field research from three national projects. One project of the Global Learning Project, the Friendship Through Education Consortium, is a consortium of non-governmental organizations and private groups committed to connecting children from different nations in an effort to bridge cultures and broaden cultural understanding. This Friendship Through Education Consortium connects with and is inclusive of: People to People International; UN's Cyberschoolbus; ePals Classroom Exchange; Global SchoolNet Foundation; Schools Online; Sister Schools international; US Fund for UNICEF; and World Wise Schools Program of the Peace Corps. In addition, Wexford Inc. with The Center for Language Minority Education and Research at California State University Long Beach (CLMER), will report information from their research on the multilingual and multinational projects, Mathematics in Our Lives and Water, Water Everywhere. All of these national and international projects are examples of cyberspace serving as a learning space for cultural interaction by faculty and students from around the world. In particular these projects are exemplary because they demonstrate: students involved in decision-making regarding tough issues of national and international scope; students around the world developing a sense of responsibility and teamwork; teachers and students learning new concepts together in a constructivist learning environment; students learning through topics they chose and that are closely related to their lives; use of telecommunications for the betterment of mankind. In addition these initiatives from the Global Learning Project involve parents as active partners and involve parents as valued members of the global learning team along with teachers and students. Detailed findings from all of the above initiatives will be discussed.

The Borderlink Challenge Initiative is a partnership between the Imperial COE and the San Diego COE with the purpose of improving post-secondary opportunities of students. One particular powerful component of the program is the online AP Coursework. This initiative has provided numerous students in California with the opportunity to access AP courses that without the program would not be realized. The completion rate for this program is extremely high because of the following factors with students: helping each other; having strong study habits; are independent learners and are highly motivated; make use of their coaches; have strong English skills in reading and writing; and keeping up with schedule of course and not getting behind. Information from a smaller sample shows that: 94% accessed coursework from home and school; 83% took course to be more competitive for college entrance; 78% wanted to try something more challenging; and 72% wanted to work more independently. Detailed findings form the report will be discussed.

The third initiative that will be reported is the American Association of University Women (AAUW) Study of Women Learning Online (www.aauw.org/2000/3rdshift.html). Over 500 women and men were surveyed or interviewed for the study. Findings include: online learning is on the rise and 60% of these nontraditional online learners are over 25 years of age and female; the majority of those surveyed had educational goals and aspirations similar to traditional students; majority had anxiety about fulfilling their other roles and having to study, conduct research and write papers; virtual classroom minimizes the discomfort and alienation that these students feel on traditional college campuses populated by 18-22 year olds. The Women in this study give distance learning high marks for family and flexibility as they can be home for their family, cab learn at their own pace and do course work when they can fit it in with their busy schedule. It was also found that the online learning situation decreased the cost of their education saving money and time on commuting and childcare. Women also found that they found new fulfillment from obtaining a degree or gaining useful knowledge for the workforce. Some negative issues were the cost of tuition and equipment and the often difficult course-load. They also found that not all the distance education courses were accredited. With this we have found that we need to expand financial and programs to support part-time students with small course leads. We also must involve more women administrators, teachers, and students in the planning process for online courses. Education is needed for

BEST COPY AVAILABLE

policy makers so they understand the difficulties of working mothers who are seeking to continue their formal education online. Information from this study needs to be broadly disseminated to groups that support women and their needs.

Qualifications of panelists

Sheila Cassidy is the Executive Director of Wexford Inc. a private not for profit organization that specializes in the evaluation of large-scale technology initiatives. Wexford Inc. The WEXFORD Institute assists agencies and individuals to collaborate to solve educational issues, to create equitable and excellent educational opportunities for all learners. WEXFORD is recognized nationally for its work in collaboration, strategic planning, evaluation, and equity. Sheila Cassidy has 25 years experience as an evaluator. She is committed to equity and excellence in education for all students, with a focus on the traditionally underserved, particularly children of color, language minority students and students from low income families. Sheila has been a teacher in Philadelphia, Pennsylvania and Compton, California, as well as an administrator of bilingual programs in Lawndale, California. She completed her doctoral coursework at the University of Southern California in Curriculum Change and Evaluation. She has conducted research and evaluation for local, state, regional and national agencies and programs.
Over the last decade, Sheila has assisted agencies in program development (planning, design, funding, implementation and evaluation). Sheila has authored instructional materials, evaluation and research reports and articles. She co-planned and facilitated the 1997 Distance Education Forum, the 1998 Distributed Education Forum and the 1998 Educators Summit on Evaluation of Technology Integration and Distributed Education, sponsored by the Office of Educational Research and Improvement in the U.S. Department of Education. Sheila is the co-author of "*Developing a Vision for Distance Education in the 21st Century.*"

Selma L. Sax is the Senior Consultant of the SAXTON GROUP, a firm which offers consulting services to business firms and educational institutions throughout the United States. She is currently working with Wexford, Inc.as a Senior Evaluator, Director of Policy Initiatives and Co Director of PT3•L3 "Learning, Linking and Leading", Wexford's 2001 Catalyst Grant funded through the Preparing Tomorrow's Teachers to Use Technology grant program at the United States Department of Education. Mrs. Sax holds a degree in Education from the University of Massachusetts at Boston, did her graduate work at California State University at Los Angeles, and holds both California and Massachusetts teaching credentials. She was a high school teacher, counselor and psychometrist for Los Angeles Unified School district for 9 years and served as a locally elected school board member for eight years, serving as president of the board twice.

In 1997, Governor Wilson appointed Mrs. Sax to the California Education Council for Technology in Learning and reappointed her in 1998 for a second term. She served for over two years as the Chairperson of the Council. More recently, Mrs. Sax worked with Policy Staff for President George W. Bush to help formulate the policy initiatives for the educational technology section which was written as part of the "No Child Left Behind" ESEA Reauthorization legislation in 2001.

Deborah V. Jolly is a Senior Research Scientist with Texas A&M University and directs the College of Education's Governmental Relations Initiative. Dr. Jolly has lead man national and international research efforts in the area of educational technology. She has vast experience in K-12 education, special education, school administration and university research. She has been a private business owner in the high tech field and has held senior management positions with a national regional research laboratory.

Portraying Yourself Online:
A Discussion of Teaching Styles in Online Courses

Dr. Susan M. Colaric, Assistant Professor, Educational Technology (moderator)
Dr. Plummer Alston "Al" Jones, Jr., Associate Professor, Library Science
Dr. Diane D. Kester, Associate Professor, Library Science and Educational Technology
Dr. Sue Steinweg, Visiting Professor, Special Education
East Carolina University, Greenville, NC, USA

Abstract: It is clear that more courses are being offered online each year. With the increase in the number of courses offered, the number of faculty teaching at a distance will also be increasing. Many researchers are discussing concerns that faculty have about online courses, such as incentives, training, technical support, workload, and intellectual property. Yet an additional area of concern may be holding many faculty back. The thought of transferring their teaching style to an online environment may be impossible for some faculty to imagine. This panel discussion will involve four faculty members who currently teach online in various subjects. Each will present information on his/her teaching style, both classroom based and online, and discuss any differences in assignments and assessment.

It is clear that an increasing number of institutions have begun offering distance learning. Among public 4-year institutions, 79 percent reported offering distance education courses in 1997-98, and an additional 12 percent planned to offer such courses within the next 3 years (NCES, 1997). Total enrollment in distance education courses across all postsecondary degree-granting institutions approximately doubled from 1995 to 1997-98, from 754,000 to 1.6 million (NCES, 1999). Institutions cite various reasons for offering distance education courses delivered through the Internet or other audio/video media (interactive or one-way). Among the goals are increasing students' access, increasing enrollments, increasing the institution's access to new audiences, and improving the quality of course offerings (NCES, 1999). In fall 1998, 6 percent of full- and part-time instructional faculty and staff at degree-granting institutions indicated that they taught at least one class or section through a distance education program; however with the increase in courses offered, the number of faculty teaching at a distance will also be increasing.

Many researchers are discussing concerns that faculty have about online courses, such as incentives, training, technical support, workload, and intellectual property. Yet an additional area of concern may be holding many faculty back. The thought of transferring their teaching style to an online environment may be impossible for some faculty to imagine. Grasha (1994) defines teaching style as a "pattern of needs, beliefs and behaviors that faculty display in their classroom". A faculty member's style affects how information is displayed, how student interaction occurs, how classroom tasks are carried out, and how assessment occurs. For instance, a faculty member who categorizes herself as an "Expert" believes that she possesses knowledge and expertise that the students need. Her main concern is with transmitting information and ensuring that students are well prepared (Grasha, 1994). The eighty-three percent of faculty who recently reported using lecture as their primary instructional method (NCES, 2001) would probably fall into this category. In contrast, a faculty member who considers himself to be a "Personal Model" oversees, guides, and directs students by showing how to do things and encouraging students to observe, and then emulate, the instructor's approach (Grasha, 1994). Is one teaching style more appropriate for online learning or should each faculty member be encouraged to express his/her own teaching/learning philosophy online?

This panel discussion will involve four faculty members who currently teach online in various subjects. Each will present information on his/her teaching style, both classroom based and online, discuss any differences in assignments and assessment, and present ideas of how they came to have that teaching style.

BEST COPY AVAILABLE

The discussion will then be opened to the audience to address a number of controversial issues in e-learning in higher education:

- Do faculty members need to change their teaching style when moving to an online classroom?
- How difficult would it be and who would decide what the "correct" online teaching style would be?
- Do the accrediting agencies have a right to dictate how online class interaction occurs?
- Is the academic freedom that a professor exercises in the classroom being jeopardized by the move to an online classroom where the content can be more readily reviewed?

Dr. Colaric's Position statement: I believe that knowledge is built by an individual, is internal to the individual, and is influenced by the culture in which the individual learns. The role of the teacher is to guide learners as they construct their knowledge by providing resources, and challenging students to build an integrated understanding of the material. My goal is to provide a learning environment, either face-to-face or online, in which students are comfortable participating in discussion and where they feel responsible for both their own, and their classmates', learning.

My face-to-face and online courses are fairly similar. Both rely on the assumption that students will obtain basic content information independently and the role of the class is to have students define, describe, and modify that information until it becomes knowledge. So preparation through reading is key and class time is for discussion. I don't consider myself to be a content expert but a facilitator whose role it is to design activities, social interactions, or problem-solving situations that allow students to practice the processes for applying course content. This isn't an easy process! Many, if not most, students are used to reading textbooks and listening to lectures and then recalling what is often disconnected and discrete bits of information. Many students are confused by my classes for the first few weeks. They aren't used to their opinion and experiences "counting" as knowledge and are waiting for me to tell them what to do. In a face-to-face class it isn't unusual for me to announce that I don't answer my own questions and then we wait through long periods of silence until some brave soul speaks up.

In online classes I've developed a number of strategies that assist me in moving students to this student-centered environment. I make very clear that class participation is an integral part of the course grade and provide them with guidelines of exactly what they need to do to earn participation "points". I start the class with an introduction dialogue that introduces the students to each other in order to build a learning community where students come to know each other. All students move through the class at the same pace based on two-week modules; this definitely isn't a self-paced course. And I model appropriate communication strategies throughout the course.

Dr. Jones' Position statement: I believe that content is the most important consideration for a course and that the majority of my time as a teacher should be involved in making sure that it is relevant. I realize all too well that I depend on my technologically savvy colleagues for help in getting the content online. I'm still amazed at the mysterious ftp process and the capabilities of servers to store and distributed the information I create.

My philosophy of teaching students is based on the assumption that students in my classes are true beginners. I assume that they know nothing or very little of the content to be presented. I believe that all students are individuals and I try to take into consideration that their approaches may be vastly different from my own. I try to give my students practical knowledge that can be used as the building blocks to add to the lifelong process of building upon prior knowledge.

My courses are self-paced totally. Students have a deadline when everything must be completed. I am available online through a conference center as well as via e-mail, telephone, and fax to coach them through their assignments and amplify what they are introduced to in their online class materials. I hold physical as well as virtual office hours.

The assignments for all of my classes require the students to apply what they are learning to their own situations. I feel that students need and often do not have hands-on experience. The assignments allow them to get involved in real life situations where the information they are learning can be applied toward solving problems in various library settings. As a confirmed pragmatist, I design my students' assignments to be practical in nature. I want what I present my students, either online or face-to-face, to be applicable to their particular library settings.

I love to teach and see the advantages of teaching students who have busy schedules and lives outside my courses and live in remote areas not readily accessible to ECU's campus. I see online teaching as a means of removing barriers and making the formerly impossible now not only possible, but also readily accessible via the Internet.

Dr. Kester's Position statement: Some have called me a pioneer in moving from face to face teaching to totally online teaching. The content of the first course I delivered over the Internet was an introductory course about the Internet. What better way for students to learn the content than to experience it first hand. That first year, I held a two-hour hands on session to be sure students understood the terms. These terms included telnet and gopher. The students found it difficult to move from the well-equipped computers of the university lab to their own personal computers with dial-up access. That was the last time I held such a preliminary session for a class.

My students have always been non-traditional adults in graduate courses. Knowing the difficulties of juggling work, home, and school, I began each class with a global overview of the expectations of the semester. Assignment deadlines were flexible, except for student presentation dates. I use the same teaching style online, with some modifications. I use general deadlines that are meant to help students move through the course and not get behind. Units cover two to four weeks, providing flexibility during that time.

Over the past six years I have developed eleven different courses for online delivery. Gradually, most of these courses have been turned over to new faculty members, giving them a model to use during their first year of teaching online with the opportunity to revise to suit their own teaching style. Our students live in rural areas with slow Internet service; therefore, I have kept the design of the courses simple - no frames, few graphics, no streaming video. For our audience this has lessened the technology anxieties and allowed students to concentrate on the content. My instructional strategies include pairing, small groups, threaded discussions, and some synchronous chat. Assignments are designed for performance based assessment. Field visits to schools and libraries to gather information are followed by reflection on what was observed. Projects are designed to allow students to prepare for their future (and sometimes current) work setting.

When teaching face to face, I knew each student by sight, but could not always recall their name. Teaching online, I know students by their personalities, their email tags, and their style of writing in our "15 minute break" discussion threads. It is always a thrill to finally meet students at conferences or even on graduation day.

Dr. Steinweg's Position statement: My first experience with online instruction was exciting, frustrating, and arduous! Everyday there was a new challenge. I found that the students were hampered in accessing the content by their lack of technology skills. It seemed that I spent a great deal of time dealing with technology issues. The very structured, content-focused nature of the course design left me feeling that I was keeping records. I couldn't seem to get beyond the mechanics and in some way interact with the students. I felt like I was the grader in a self-paced, programmed instruction manual. Getting the content across was important, but I wanted a way to "talk" with the students.

I was fortunate to be asked to teach two sections of this same online class in the Fall semester. I took the course that had been designed and tried to tweak it to make it fit my style. I wanted to be able to interact with the students. I wanted them to interact with each other. I felt that we all had information and experiences that could add to the understanding of the content.

Teaching style is probably what I am really trying to say. In a face-to-face class, I like to have a lot of classroom interaction. I don't feel comfortable with the role of "dispenser of knowledge". I do feel that it is important that the factual information is presented, but I feel that the students can obtain a lot of that from the text. What I want to do is to get them to apply the facts to real world situations in which they are working. I also want them to see that there isn't always one right way or answer.

Because my topic is about exceptional children, I feel it is important for the students in my class to actually see children who are exceptional learners and to understand that we are talking about people, not just numbers. In my face-to-face classes, I usually use video clips to generate some discussion. I often invite practitioners in the field to come and share information about their work with exceptional learners. Students are required to give group presentations on a topic they have researched.

Trying to transfer some of this into my online class was a challenge. Because our university serves a large rural part of the state, many individuals are accessing the course through modems at home and video can be a problem. This also has an impact on the use of synchronous chats. Fall semester I changed a few things, but I still didn't feel comfortable. Students were beginning to interact minimally on the Discussion Board. But I still had this feeling of isolation in the course.

This semester I am teaching two online sections of the same introductory class and one section of another graduate level special education course that is taken primarily by students seeking a MAT. Another instructor had designed this course and I was teaching it the way that it had been designed. I decided to sign-up for an online class in strategies for online instruction. Teaching two online classes designed by two different people and taking an online class afforded me the opportunity to observe lots of different techniques, some of which addressed the things for which I had been looking.

I learned some ideas to generate conversation and to have students do online presentations. I began to see the interaction among students, and to even see them supporting each other. Rather than having students send all of their assignments to me, I started having them post their work on the discussion board so that classmates could ask questions and offer comments. I started using case studies to get the students to think about real situations with exceptional learners.

I will have to add that I have begun to think that I like teaching online better than face-to-face due to the time it allows for reflection and the multiple opportunities to view the information. In a face-to face class, the conversation is here for a second and then it is gone. Even notes do not completely record what happened. In an online class, the conversation and other information is there to be accessed repeatedly. The student or instructor can view the conversation, think about it, and then respond. This seems to generate higher level thinking.

What I am beginning to see is that I don't have to change my style to teach online. I just have to explore and find ways to use technology that allow me to do what I want to do. My technology skills are limited, but I am learning fast. Observing what other teachers have done online really helps. I can be just as supportive and encouraging online as I can be face-to-face. Trying new things is scary and exhilarating!

Strategic Focus: Many are relevant to this issue.

Presentation Title: eDropouts: Reducing Attrition in Online Learning

Presentation Description

Instead of, "If we build it will they come?" maybe we should be asking, "If they come will they stay?" The dropout rate in distance learning is generally reported to be higher than that for traditional classroom based learning. Those engaged in online distance learning must grapple with the problem of online learning dropouts. We need to identify innovative approaches and technologies that directly address the causes of attrition.

The reasons dropouts give for discontinuing distance learning are many. Common reasons include:

- Lack of prerequisites (academic preparation)
- Personal or domestic reasons
- Insufficient time available for study
- Job related issues
- Financial issues
- Care of children and or other domestic demands
- Change of plans
- The nature of the courses offered or the teaching methods
- Lack of academic counselling and support
- Isolation (loneliness and lack of interaction)
- Illness
- Unsatisfactory leaning or study conditions
- Lack of motivation and lack of confidence

Many educators and corporate trainers have offered suggestions for reducing attrition in online distance learning. Some of these suggestions include:

- Improved learner preparation
- Time management
- Learner goal setting and self assessment
- Increased interaction (discussion forums, chats, simulations, etc.)
- Mentoring and support
- Hybrid models (mix of face-to-face and online communication)
- Improved content quality

I propose to host a panel of three or four online educators and/or corporate trainers to examine the reasons learners give for dropping out and to explore innovative methods and technologies that may reduce attrition.

Ready to Roll: Go to Market Smarter.

Abstract:
Product shelf-life keeps getting shorter with constant upgrades and new releases rapidly replacing the previous generation. The speed-to-market marching order can only work if everyone across the organization is up to date on the latest product offering. That means getting new product knowledge to the right people right away, from marketing to sales to support staff, to maintain the competitive advantage of rapid product life cycle.

In this panel presentation, Ara Ohanian and representatives from Black and Decker, Toyota and The Hartford will examine how product education can be shaped as a marketing weapon that can sharpen competitive edge, increase sales and build customer loyalty. They will discuss how companies can extend the reach of proprietary business intelligence to create a smarter sales force, and thus quicken market penetration. Citing the importance of training beyond product functionality, the speakers will describe how companies can keep personnel up to speed on current value propositions, market positioning against competitors, and sales strategies. The speakers will discuss how Vuepoint deployed educational tools to maximize knowledge acquisition and management across the organization to achieve speed-to-market sales objectives and product support readiness.

Attendees will learn:

- Critical role of education for product roll-outs
- How compressed speed to product knowledge can generate more sales and increase revenues
- How to rapidly ready the organization for new product roll out and upgrades
- How formal policies and practices for creating, capturing, and sharing proprietary knowledge can help build and reinforce brand awareness and identity

Speaker contact info:
Ara A. Ohanian, Chief Executive Officer and Founder
Vuepoint Corporation
Four Expressway Plaza
2nd Floor, Roslyn Heights, NY 11577
(516) 390-8800

Speaker bio:
Ara Ohanian brings more than 10 years of international corporate training, and knowledge transfer experience to his position as CEO and Founder of Vuepoint Corporation. Prior to founding Vuepoint, Ohanian founded management programs with the late Nobel Laureate Dr. W. Leontief to provide just-in-time training to over 2,500 international executives in more than 10 countries. He also established and ran a successful series of entrepreneurship programs to train citizens of the former Soviet Union for the United States Agency for International Development (USAID) under a contract from Deloitte & Touche.

Ohanian also has extensive sales and marketing experience that began with his position at NCR corporation where he ranked #1 in overall sales for the organization. In addition, he worked in advertising and marketing for Amacon, a UK based company representing brands such as Kellogg and Clorox.

Ohanian received a BA from the City University of New York as well as a French Baccalaureate from the Universite de Lille. He is conversant in more than 5 languages including French, Armenian, Spanish and Russian. A member of the Learning Content Management System (LCMS) Vendor Council, Ohanian also co-founded the eLITE (Electronic Learning Incites Teaching Excellence) Think Tank, an independent educational and research organization dedicated to advancing knowledge and thought leadership in eLearning.

Recent speaking engagements include: Human Resources Technology Conference and Expo, eLearning Executive Leadership Conference, Online Learning Conference and Expo, and Training Director's Forum.

Recent articles about Ara Ohanian:
Ohanian was quoted in the May 2002 issue of CFO Magazine in an article entitled "Web Learning Still a Class Struggle,"which describes how Toyota implemented Vuepoint's eLearning software as an effective management tool to increase productivity, and sharpen competitive advantage with faster speed to market for new products and services
<http://www.parsintl.com/pdf/4539-CFO.pdf>

Ohanian was the subject of an interview with CEOCast.com:
<http://www.vuepoint.com/news/ceocastInterview01.pdf>

July 2001 Training Magazine article:
<http://www.vuepoint.com/news/knowledge_race.pdf>

August 2001 EdVentures.com article:
<http://www.vuepoint.com/news/eduventures0801.pdf>

In August, 20021, Ohanian was nominated for SmartExecutive's eLearning Executive of the Year Award alongside renowned CEOs including Jack Welch of General Electric, John Chambers of Cisco Systems, Larry Ellison of Oracle, and Bill Gates of Microsoft.

Advantages of the Various Online Course Designs

Raymond M. Rose
Concord Consortium
United States of America
ray@concord.org

Zahrl Schoeny
Curry School, U Virginia
United States of America
zgs@virginia.edu

Alese Smith
United States of America
alese@concord.org

Abstract Online learning as a term includes many different approaches and technologies, but there's little that's been done thus far to identify the effectiveness of the various approaches, and offer guidance to those who have been told to "do something with online learning." There are advantages and drawbacks to the various online strategies. This panel will explore the relationship between learning outcomes and elearning course design.

Online learning is a very inclusive label, but used as if it were a single thing. It is not, and the range of approaches, whether based on technology or pedagogy are vast. There has been little done to help those considering online education to differentiate between the various online education approaches. Currently the arguments seem based more on vendor and vendor products, than on the learning outcomes expected by the content developer.

It's no surprise then that many online courses don't seem to meet the needs of the participants or the course developers themselves. What's needed is a discussion about the efficacy of the various elearning approaches, and how to match learning objectives to those approaches. In doing so, there is far more likelihood of developing an effective online learning experience for all concerned.

Online courses are frequently characterized as synchronous or asynchronous; but there are other dimensions. Instructor-led is frequently associated with linear-sequential structure while non-instructor led programs have greater potential for non-linear structures , but none of those characterizations provide any sense of which strategies hold the greatest potential for economically achieving a particular set of learning objectives. Conversely, what's the best online approach for developing knowledge on a topic that can be applied to a variety of diverse situations? It's time to being the discussion.

The three panelists -- Alese Smith, Zahrl Schoeny, and Raymond Rose -- come to this panel with over 15 years of experience in online education.

- Alese has been an online course developer with the Concord Consortium, and was one of the lead developers in creating the online teacher professional development course for the internationally recognized Virtual High School program. She has helped design a variety of online courses. She is co-author for Concord's new book; *Essential Elements: Prepare Design & Teach Your Online Course.* She is a strong believer in asynchronous courses.
- Zahrl is an advocate of blended online course delivery. He developed an online professional development program for school administrators in Virginia. He is in the process of developing a new online program that will prepare online course designers. Zahrl was part of the expert panel that developed the online course delivery standards for the Virtual High School.
- Ray has been the leader of Concord Consortium's online efforts over the past seven years. He currently directs Seeing Math a project that uses video case studies as a primary strategy for teacher professional development. Over the course of his work with Concord he has been involved in projects using a variety of online delivery techniques. He helped develop the NSCD Standards for Online Teacher Professional Development, and is on the board for a number of online education projects. He was recently recognized at the tenth annual Marketing Opportunities for Business and Entertainment Conference as one of the Influencers and Innovators of the Internet and Technology. He is a recognized proponent of online asynchronous education.

Abstract: The panel will address the topic of eLearning from the adult learner's point of view. The objective is to expose the motivational, cognitive, metacognitive and social efforts required to succeed in an on-line web-based learning environment (WBLE). The panelists will describe strategies implemented in academic, workplace and military fields that support self-directed learning (SDL) skills required by eLearning. Discussion with participants will help designers, teachers, and human resource officers understand the importance of supporting self-learning skills in order to provide authentic and efficient access to eLearning. The discussion will also propose supportive solutions to alleviate the difficulties faced by the eLearner.

Key words : **eLearning, self-directed learning, web-based learning, learning skills, instructional design**

A new role for the eLearner

Distance learning, multimedia information processing, and network collaboration are three features of eLearning that create flexible and open-ended learning environments, which in turn put the learner into a controlling position of the learning process (1).

Due to the distance between the teacher and the learner (2), the adult learner needs to be able to set priorities and plan of actions, set a time schedule, organize the environment, assess his learning progress and accurately diagnose the problems and find help to solve the problems.

In processing multimedia information (β), the learner needs to be able to evaluate continuously one's own knowledge in order to decide which information to search, express appropriate search strategies, take on the teacher's role to create the accurate knowledge links.

When collaborating with peers (4), the learner needs to be able to manage teamwork and/or group work, negotiate acquired knowledge with others, validate the others' knowledge and communicate results to the team/group.

BEST COPY AVAILABLE

This leading position involves a particular set of learning skills and requires innovative conditions for successful learning (5).

Difficulties to assume

ELearning puts the learner in a proactive position in order to progress and succeed. To adopt this position may be confusing for most adult learners of today because it requires the application of high level (SDL) skills such as planning, self-monitoring, self-reviewing, self-discipline and self-confidence (6). These skills were unfamiliar in traditional learning (7) and in an eLearning situation new components make them more complex due to the combination of distance, multimedia and network collaboration (8). For example, to manage one's rhythm of learning in an asynchronous and collaborative setting is different than in a classroom setting. It is also different to control one's comprehension while reading a print book than while searching and consulting web pages on a specific topic.

To succeed as an eLearner one has to accept the additional effort required by eLearning conditions. One has to mature in learning.

Strategies to support the eLearner

If SDL is an important set of learning skills to master in eLearning, it is also an important source of difficulties mainly related to a low awareness of eLearning conditions and to a poor mastery of comprehension and time management (9) (10) (11) (12). These difficulties can be related to personal or organizational constraints and the high drop out rate in distance education shows that it is crucial to address this problem with efficient support strategies in order to allow the eLearner to succeed and adopt eLearning.

The panel will allow the participants to discuss five different support strategies using one or more of the following resources : the assistance of an eFacilitator and peers collaboration, a training plan to develop the SDL skills and the use of interactive self-management tools embedded in the WBLE. These strategies were implemented in academics, workplace or military field and the possibility to adapt them to other environments will also be considered.

Self-management Tools to Support the E-Learner's Self-management Process

This strategy aims at supporting the SDL process through the use of tools embedded in a WBLE (http://www.licef.teluq.uquebec.ca/anglais/index.html). A skill profile, a workplan and a progress assessment are tools designed to inform the eLearner about the main learning conditions which are the knowledge content, the learning events, the time schedule, the motivational, social and technological resources available. They allow one to prepare a workplan, self-monitor, review and adjust the plan according to the on-going progress. At the user's request, self-management strategies can be supplied as well. These tools were designed according to a conceptual model of eLearner's needs for support and they have been used and tested with adult eLearners in academic and workplace settings. The presentation will emphasis the link between the model and the tools and the adaptability of these tools to various settings will also be discussed.

Motivational Strategies via Technology to Enhance Self-directness, Performance, and Satisfaction

This discussion concerns a large scale study (13) (14) at the U.S. Military Academy on integrating technology-mediated motivational strategies to enhance self-directedness, performance, and motivation of cadets. The motivational strategies are communicated via email messages, with a link to content-related strategies intended to encourage the learners to self-direct by accessing the material (web-based simulations, online quizzes, PDA-based content) on their own time and outside the requirements of their courses. Post-strategy SDL surveys are used to determine whether or not cadets accessed the material, if not, why not; and if so, whether their curiosity to learn was piqued, how beneficial they feel it is to learning the course content, and open ended questions asking them for further input on the strategies. Readiness for Self-Directed Learning (as measured by the SDLRS instrument) was also measured.

A Self-Directed Learning Perception Scale to Guide the Design of Supportive Self-Directed Learning Environments

Online learning involves much more than transferring knowledge to learners. The Self-Directed Learning Perception Scale (SDLPS) (15)(16) is a tool which lets facilitators and course designers move beyond the "bells and whistles" of what computers can do to build supportive online self-directed learning environments. The SDLPS is a questionnaire that gives a snapshot look at online learning experiences to show if opportunities exist for learners to address individual needs, develop more responsibility for their learning, experience a non-threatening learning environment, interact with others and develop relationships. Numerical scores and practical suggestions for building even more supportive online learning environments are part of the SDLPS feedback.

Support Strategies to Design Environments that Enhance Desire, Resourcefulness, Initiative, and Persistence in Learning

This presentation will provide a conceptual model (17) (18) for understanding learner autonomy and autonomous learning within the confines of self-directed learning specifically within an eLearning environment. Autonomous learning is the process in which the learner makes an intentional decision to assume the responsibility for a learning situation. The concept of autonomy can be placed within the framework of personal attributes. Thus, within this structure, learner autonomy can be identified and understood as the characteristic of the individual who exhibits agency or intentional behavior with respect to their learning endeavors. Learner autonomy is one of the personality characteristics associated with autonomous learning (i.e. desire, resourcefulness, initiative and persistence). Facilitating and developing learner autonomy in any environment is challenging but even more so in distance learning. Strategies to enhance and develop learner autonomy with the idea of facilitating the move from learner dependence to learner independence will be discussed and will provide a conceptual model for understanding learner autonomy and autonomous learning within the confines of self-directed learning.

A SDL Classroom-based Program to Enhance the Ability and Comfort with Self-directed Learning Activities such as E-learning

The classroom-based program (12) (19) is a transition strategy that utilizes organizational definitions and policies, personal analysis instrumentation such as the SDLRS, and self-directed learning contracts to provide new eLearners with information and a support structure that will give a chance to practice learning on their own as well as involve their supervisors in the process.

A Successful Online Education Program Panel Discussion

Kaye Shelton, Online Education, kayeshelton@sbcglobal.net
Dallas Baptist University, USA

George Saltsman, Educational Technology, saltsman@acu.edu
Dr. Paul Lakey, Scholar-in-Residence, Walter Adams Center for Teaching Excellence, lakeyp@acu.edu
Raye Lakey, Faculty Development and Instructional Development, lakeyr@acu.edu
Abilene Christian University, USA

Abstract: "How did you do it?" "What makes your online education program so successful?" "How did you get your faculty to agree to teach online and your administration to support the funding?" "How do you get the students engaged and complete the class?" Repeatedly, education professionals pose these questions at many conference and workshop presentations. Afterwards, the subsequent email and phone calls to the panelists confirm the overwhelming need for solutions to these issues in online education and academia today. There is no single prescriptive solution; however, successful online education programs do exist and share many common practices. Based on first-hand experience and a review of successful models, the presenters will offer guidelines for educational institutions and professionals who seek insight into the complexities of online education. This presentation will serve as an excellent resource for creating an online education program or for improving a struggling one.

Panel Discussion

"How did you do it?" "What makes your online education program so successful?" "How did you get your faculty to agree to teach online and your administration to support the funding?" "How do you get the students engaged and complete the class?" Repeatedly, education professionals pose these questions at many conference and workshop presentations. Afterwards, the subsequent email and phone calls to the panelists confirm the overwhelming need for solutions to these issues in online education and academia today.

There is no single prescriptive solution; however, successful online education programs do exist and share many common practices. Based on first-hand experience and a review of successful models, the presenters will offer guidelines for educational institutions and professionals who seek insight into the complexities of online education. This presentation will serve as an excellent resource for creating an online education program or for improving a struggling one.

This panel discussion contains frameworks of information for three specific audiences: educational leaders, program directors, and faculty/course designers. The audience will gain a general insight into the overall design of an online education program, and will also be provided with detailed information tailored for their specific areas of focus.

This presentation will be based on the presenters' significant experience in working with online education, faculty support, and educational technology. They will offer concise accounts of their own pioneering efforts and knowledge gained through academic study. Case studies, sample documents, expert advice, and pertinent debates of pedagogical issues will support the presenters' rationale. The panelists will offer examples of what works and humorous illustrations of, all too often, what does not. The audience will gain valuable knowledge from insight and experience in online education, surveys of academic professionals, and interviews with key people in both successful and struggling online programs.

Primary challenges such as program leadership, setting goals and objectives, faculty development and support, instructional design, and online teaching recommendations will be addressed. Each challenge will be presented with successful strategies that have worked for different institutions. No single, universal

BEST COPY AVAILABLE

method exists to tackle the many challenges of an online program. Institutional culture, differing goals, and attitudes toward technology will suggest varying solutions that institutions can utilize effectively.

Many established institutions have found that creating an online education program is a struggle. Years of deep-rooted tradition, resistance to change, lack of understanding about the medium, and the fear of loss of academic reputation and quality have either caused schools to be slow in accepting this medium or have caused fatal errors in program design.

The presentation will address four critical areas of online education:

1. Leadership Models: Why They Are Important
2. Setting Goals and Objectives
3. Faculty Development/Online Instructional Design
4. Online Teaching Recommendations

In addition to these four critical areas, the panelists will be prepared to lead discussion regarding other important areas of online program design such as: preparing the institutional infrastructure, accreditation issues, selecting an online courseware management system, marketing the program, selection and retention of online students, and online student support.

Leadership Models: Why Are They Important? This discussion will concentrate on the need for upper-level administration support and faculty buy-in. One of the paramount truths of building a successful online education program is that it must have top-level administrative support. We will propose several leadership models and will examine their advantages and disadvantages. Examples will be cited where programs floundered or failed because the upper-level administration failed to give adequate support to the program. Positive examples will be given where strong leadership removed the obstacles and a successful program developed.

Setting Goals and Objectives. This discussion will address the institution's goals, scope, and objectives. The purpose of this discussion will be to persuade the audience to define the institution's overall purpose for creating the program. Methods will be presented to establish objectives that are both realistic and obtainable. The ideal method for goal setting is to form a group of interested individuals, preferably from both academic and administrative departments. The group should be kept small but diverse with representation from each of the key areas involved such as admissions, registrar, faculty, advising, information technology, and key administration. This important group of individuals analyzes the critical issues and discusses program direction and rate of growth.

Faculty Development/Online Instructional Design. The presenters will cover valuable aspects of faculty support and online instructional design. Preserving academic integrity and the rigor of online instruction is critical for quality online education. Faculty must be supported in this new method of teaching. Instructors should not be expected to learn by trial and error. Not only will the students suffer, but also the instructor will have a dissatisfactory experience and may never return to teaching online. A sample web style course guide will be presented as well as sample course designs and instructional recommendations. A variety of methodologies, pedagogy, and curriculum design issues will be discussed for the course designer. Methods will be presented for designing online courses including procedures for asynchronous learning including a web content chunking approach. Also included will be a list of excellent resource texts and websites for both instructors and course designers.

Online Teaching Recommendations. This important discussion will suggest successful techniques for online teaching and classroom facilitation. An online education director must be keenly aware of the changes and challenges that face faculty in this new instructional medium. Creating policies and procedures for teaching and learning online is a complex task. This topic will provide sample policies, online classroom guidelines, and Internet etiquette behavior suggested by successful online education professionals. For example, will an instructor know how to manage an online student who speaks sharply in a threaded discussion or verbally attacks the instructor in front of the class? This is difficult to deal with in

BEST COPY AVAILABLE

the traditional classroom, but eliminate the physical presence of the student and instructor (and with that, a layer of communicative clarity) and it becomes even more difficult to control.

The online learning community is a critical development strategy for encouraging online learning, especially at an asynchronous level. Students must feel comfortable with posting their discussion replies and gleaning knowledge from each of their classmates. The presenters believe the instructor is ultimately responsible for creating and nurturing this community of online learners and thus will need resources and strategies in which to create this important element of the online course.

Discussion Format – Each panelist will address one of the four critical areas of online education. Audience participation will be encouraged, as the panelists' desire for this discussion is to equip the audience with pertinent information that can be taken back to their own institutions and put into place to help successfully create or improve an online education program. Adequate time will be allocated for numerous audience questions.

Panelists Background

Kaye Shelton, MSEd
Topics covered: *Instructional Design, Online Teaching Methodologies, and Courseware Management Systems*

Kaye Shelton is the Director of Online Education for Dallas Baptist University, a university instructor, and an online education consultant. A certified online instructor, her education includes a BAS in Management of Information Systems and an MS in Education emphasizing Online Teaching and Learning.

Mrs. Shelton is employed as Director of Online Education at Dallas Baptist University. After accepting the challenge of developing an online degree initiative in 1998, in the setting and culture of a traditional Christian liberal arts college, the program resulted in prominence and success. Fighting ingrained culture, resistance to change, and the retraining of faculty, Mrs. Shelton helped lead the online program to an enrollment of over 900 students in just three years. She continues to train instructors in the design and teaching of an online class. The online program rivals the traditional program in quality, academic integrity, and financial stability. This popular online program carries a prominent level of respect among peer institutions.

Mrs. Shelton is a university instructor who has developed and taught classes online. She enjoys teaching online, teaches throughout the academic year, and receives exemplary ratings of evaluation from her students. Mrs. Shelton has presented at numerous conferences and workshops including CITE, Stop Surfing Start Teaching, Blackboard Users Conference, and the Datatel Users Group Conference on the topics of the creation of an online education program and the best methods for teaching online.. She is regarded as an opinion leader in the field of online learning and distance education and has served as an advisor to online education programs for peer institutions. Currently, Kaye Shelton and George Saltsman are co-authoring a book concerning online education program development.

George Saltsman, MS
Topics covered: *Program Leadership, Technology and Goal Setting, and Program Objectives*

George Saltsman is the Director of Educational Technology for Abilene Christian University, a university instructor, an electronic publishing and marketing consultant, and a board member of several local technology corporations. His education includes a BS in Computer Science and an MS in Organizational and Human Resource Development.

Mr. Saltsman is employed as Director of Educational Technology in the Adams Center for Teaching Excellence at Abilene Christian University. In his 13 years of employment at Abilene Christian University, he has gained vast experience in working with technology and faculty. He helps oversee the ACU distance learning program and designs and constructs computer labs and technology enhanced classrooms. He teaches appropriate technology use to faculty and consults with faculty on many complex technological issues. He is consistently recognized for his ability to make complex issues easy to understand and has a track record of leading edge technology deployment among peer institutions.

Mr. Saltsman is also the instructor for the Interactive Media course in the Journalism and Mass Communications Department at Abilene Christian University. His energetic teaching style and ability to convey technological concepts in an easy-to-understand manner have consistently earned him excellent ratings from both undergraduate and graduate students. His students have won national awards for their student-produced works and have gone on to be successful in many careers in the interactive media field.

Paul N. Lakey, PhD
Topics covered: *Program Leadership and Goal Settings and Objectives*

Paul Lakey is the Director of the Human Communication Division at Abilene Christian University in the Department of Communication and Scholar-in-Residence in the Walter Adams Center for Teaching Excellence at ACU. His education includes two master's degrees and a Ph.D. with a dual emphasis in Organizational and Intercultural Communication.

He joined the ACU faculty in 1988. Dr. Lakey has received numerous teaching awards including the "Best Teacher in Abilene" award in 1998 and selection as "Educator of the Year" in the College of Arts and Sciences in 1999. His teaching specialties involve leadership, conflict management, and training.

He has presented and published articles pertaining to a range of communication issues, particularly cultural adaptation and conflict management. He is also active as a communication consultant and trainer particularly in the areas of conflict management and leadership. In his role as scholar-in-residence, a faculty development assignment, Dr. Lakey has directed initiatives in faith and learning integration, cultural diversity, learning teams, and teaching effectiveness (technology integration, active learning strategies).

Raye Lakey, MEd
Topics covered: *Faculty Support, Faculty Development, and Instructional Design*

Raye Lakey is the Director of Faculty Development and Instructional Development at Abilene Christian University. She also serves as Associate Director of ACU's Adams Center for Teaching Excellence.

Mrs. Lakey has provided leadership in faculty development and instructional development at ACU since 1991. She has developed a broad system of faculty development for the university's faculty, addressing traditional topics such as teaching strategies and portfolio development and cutting edge topics including the scholarship of teaching and online faculty development opportunities. Her active involvement in national and regional faculty development organizations has brought national recognition to the Adams Center for Teaching Excellence.

Mrs. Lakey has authored a number of online tutorials for faculty development and her work was cited in the 2001 issue of *To Improve the Academy*, published annually by the Professional and Organizational Development (POD) Network. The most noteworthy tutorial for faculty, entitled "Active Learning Online," is available at www.acu.edu/cte/activelearning. Her key areas of expertise include teaching effectiveness, instructional design, web-based faculty development, and faculty development assessment. Mrs. Lakey has conducted workshops, faculty development assessment, and consultations regarding faculty development for a number of other university faculty development programs.

Open Source Software Can Open Minds *and* Help Solve the U.S. Technical Education Problem

By Matthew J. Szulik
CEO, Red Hat, Inc.

Right now Microsoft is torturing the Philadelphia public school system. Acting on an anonymous tip, the giant software monopolist is making Philadelphia go through a lengthy and expensive audit of every computer in all 264 schools within the impoverished school system. Why? Because Microsoft heard that a teacher had illegally copied a Microsoft application onto a school computer. So now the school system must inventory every application on every computer in the system and produce proof of valid licenses for everything. I'll grant you that this is fairly typical behavior for a proprietary software vendor that must defend its intellectual property. But doesn't this seem like killing a mosquito with a nuke? If the Philadelphia schools had chosen open source software my company and others would have encouraged them to make as many free copies as they needed. The schools would have saved millions of dollars and hundreds of hours of inventory work.

This unfortunate incident is only the latest evidence of an ongoing crisis in computing and technical training in our schools.

Despite all the computer equipment and software that companies have donated to schools over the past 20 years, students are still advancing through the grades and graduating with inadequate technical skills – technical in this case being a synonym for "computing." The way things are going this will only get worse. The job market demands more skills and sophistication, while at the same time school budgets are shrinking. It's getting harder for us to provide the computing and technical skills that will be the foundation for the success of our economy of the 21^{st} century.

This seems crazy – haven't computer and software companies donated mountains of equipment and applications for years? How could things be getting worse?

I believe the problem is the underlying philosophy with which technology companies approach our schools. They've treated education as a *marketplace*, not as a *responsibility*. Technology companies, particularly those that create and sell proprietary software, see educational institutions in terms of market development. They think: "hook the kids today on our applications and they'll stay with us forever. They'll have to – we're the only source for upgrades and fixes."

A proprietary software company sells a school their wares (often at an attractive discount) and locks them in. The school system must return to that vendor for upgrades, bug fixes and service. Even if school staff or students possess the technical skills to repair, customize or improve the software they can't. The restrictive licenses that encumber proprietary software make it a crime to do anything with it but use it – or call the vendor and pay for help.

I want to be clear in stating the problem: by extending their lock on the educational system the proprietary software vendors have restricted choice, institutionalized inefficiency and imposed artificially high prices (even after discounts) that hurt taxpayers. Your taxes are paying for the pricing practices of a proprietary monopoly.

This can eat up school budgets quickly, and there's not much budget to begin with. In the U.S. public school system the average technology budget per pupil is $104. In my home state of North Carolina, wrestling with a serious budget deficit, it's even worse: $15.98 per pupil per year. That will buy about one quarter of one Windows license upgrade, or a couple of boxes of floppy disks. It's certainly not the level of commitment it takes to prepare students to fill the one million high-paying technology jobs that are unfilled in the U.S. right now.

There's more depressing evidence if you look at other state education budgets. That's where you have to look, because federal spending covers only seven percent of the costs of public education – the states pay the rest. Think of the impact on technical education as Ohio wrestles with an $850 million deficit. Alabama had to cut $300 million out of its education budget. New Jersey, by law, must spend first in the poorest school districts. That's an admirable approach, but it will require $1.3 billion in *additional* spending in a state that is already facing a deficit. Clearly, we have to make a major change in the way we approach and fund public technical education and that starts with breaking the traditional ways in which schools spend their meager computing budgets.

So, what should we do? We should open up our school systems to the benefits of open source software (full disclosure: that's the business I'm in). We're way behind other countries in doing this. Some examples:

- In Mexico, the government's Scholar Net program is working towards creating 140,000 computer labs in schools throughout the nation. The ambitious project, scheduled for completion in 2003, uses Linux as the operating system for these school computers. Why? The director of the program estimates that software for each lab would cost $885 if equipped with proprietary Windows, or $50 with Linux.

- In South Africa, the Zingasa Comprehensive School in Umtata, an impoverished part of the country, has created a computer learning center with old 386-based computers running Linux. Unlike Windows, Linux runs very well on 386 systems. Now every student in the high school takes Computer Studies as their seventh course. Linux is also playing a key role as South Africa moves to network 28,000 schools around the country.

- In France, under the guidance of the French Minister of Education's Centre National de Documentation Pedagogique program, 350 primary and secondary schools in the Grenoble academic district are accessing the Internet through inexpensive Linux servers.

In the United States, admirable groups such as K12 Linux and the Linux in Schools Project are working hard to stretch education dollars with open source software. These are volunteer groups, however, without government support and without the resources to overcome the marketing machinery and lobbyists of the proprietary software vendors.

If the current efforts in the U.S. are insufficient, then how can we solve the growing technical education problem? I propose the creation of an Open Source Education Corporation modeled after the Civilian Corps of Engineers. I envision public educators and local school boards working together to improve the quality of local technical education at a much lower cost, bypassing the proprietary, high-cost vendors. *This will not require new government spending.* In fact, it will reduce spending through a much more efficient use of the state and federal money that is already earmarked for technical education.

Initially, I envision four primary undertakings for this organization:

1. *Open up the spending process to welcome open source software.* Most requests for proposals (RFPs) for educational computing spending are heavily skewed towards the proprietary vendors. Many of them actually specify Windows software, or Windows compatibility. That means that from the start the bidding process excludes the products that could provide equal or better utility at a far lower price. If school systems and boards of education made just this simple change – include open source software in their RFPs – taxpayers could save hundreds of millions of dollars.

2. *Target the neediest schools.* I'm on the board of a predominantly black, under-funded college in North Carolina. The students are bright, eager, full of ideas and ready to help improve our nation. They're also hindered by an inadequate computing education. The first target for the Open Source Education Corporation should be poor schools in poor areas. Paradoxically, the fact that these schools have such meager computing environments will help them benefit from open source: they are not locked in by restrictive proprietary software licenses.

3. *Create an open source hardware exchange.* Few people realize that proprietary software licenses are tied to the computer system. If you donate an old 386-based PC loaded with Windows, the school to which you donate it must pay another licensing fee to Microsoft. Your gift costs the school money and inconvenience. But if the school strips Windows off the machine and loads Linux instead (freely downloadable from several web sites) they give new life to a computer, get software that runs well on that machine, and pay nothing. An Open Source Education Corporation online exchange could match donated computers to schools that need them and help the schools get the Linux software to make them run. The proprietary vendor loses a licensing fee but a school gets a useful computer.

4. *Create and share educational applications*. By freely sharing innovations, participants in the Open Source Education Corporation could create new applications, instantly distributing them through the Internet to any school that wants them, free of charge. This will greatly reduce spending on proprietary applications while enabling students to be innovative and creative.

Open source software promotes the free distribution of technology. It encourages innovation and sharing. It promotes intellectual freedom as students work to make the software ever better – and then spread the results to other schools – legally. And with open source software school systems can pick from a wide range of vendors; they're not locked in. If a school doesn't like Red Hat Linux, there are plenty of Linux suppliers who would love to supply a school system. Innovation and competition – sounds like capitalism, doesn't it? I'd like kids to learn about capitalism – not monopoly power -- while they learn about technology.

A pipe dream? Not really – in some ways it's already happening. Today, across the globe scientists and technical educators are electronically sharing their technical improvements to open source software as they make their work more efficient. This will lead to scientific breakthroughs. Think of the educational breakthroughs we could see if we applied these principles more widely in public education!

Our failure as a nation to adequately prepare people for the challenges of the 21st century will catch up with us. Already we see the economic clout created by very well-trained technologists from China, India, Ireland, South Korea and many other nations. But through open source software we have the tools today to improve technical education, encourage innovation, enhance our competitiveness and save money all at the same time.

Isn't it time that we changed technical education from a market development program for corporations to a cost-effective priority that operates in the national interest?

The New Generation Working Force: The Homo Zappiens

Prof. dr W. Veen, W.F. van Valkenburg, prof. mr dr ir S.C. Santema, R. Genang

Abstract: In this paper we discuss the new generation of workers, the Homo Zappiens. The Homo Zappiens is led by new skills: skills to quickly scan content, skills to multi task, skills to process discontinued information and he is used to non-linear learning. These skills can be related to ways we learn and it seems that the Homo Zappiens has developed more natural strategies for learning. These skills and competencies that Homo Zappiens is developing are crucial for future citizens of the information and creative society and society should adapt to this with new ways of learning, like blended learning, non-linear learning and authentic learning.

Introduction

Corporations will have to cope with a new generation of labour force. Workers will demand new ways to professional development using technologies such as messenger, chat and e-mail programs. The traditional out-of-office training days will no longer satisfy tomorrow's demand-based learner. These new ways of learning have different attractive names, such as non-linear learning, authentic learning, interactive learning, collaborative learning, learner-centered learning (Huang 2002) and scenario-based learning, but why are these new methods better than the ones we have used for decades? In this paper, we discuss the new abilities and skills of the next generation workers. They will be the driving force for changes in human resource management.

Homo Zappiens

The change force is Homo Zappiens, the new generation that is preparing for future information and creative society. Homo Zappiens is the generation that has grown up using three devices: the remote control, the mouse and the cell. These three devices have enabled nowadays' children to deal with huge amounts of information, selecting it properly, swiftly and according to their needs. HZ is an active processor of information, using strategies to solve problems by gaming, and to communicate effectively. Homo Zappiens considers learning as playing, exploratory play (Rushkoff 1997).

Children – the workers of the future – create electronic personalities on the net communicating in three chat rooms at a time. Such chatting demands quick scanning of scrolling messages and responding adequately. Children have learnt to be trace and select information they are looking for and deal with rapid ways of communication with many. Searching the web is the most natural way for children to find information. For booking tickets for the cinema, buying CD's, downloading music files, and also finding about the latest earthquakes or pictures of the Hubble Telescope. Online presence is just as normal as onsite presence. Using technology for learning goes without saying. Such abilities and skills are critical in an information society where knowledge is changing rapidly.
Homo Zappiens also differs from former generations in the way they play games. Instead of playing games according to fixed rules, they like to invent their own games and set their own rules. Most of the time these games do have neither winners nor losers. Nowadays kids like to determine their games like Casper and Hobbes. Casper ball is much more fun than baseball. Homo Zappiens is trying to push new sports such as skeelering and snowboarding. Sports that challenge them to explore the edges of laws of nature and the human body. They search actively for new equilibriums.
It is also the generation that considers school as a meeting place for friends rather than a learning environment. School does not challenge them sufficiently for learning the way they have been accustomed to. Of course, children who are used to be in control and to be active do not suit 'chalk and talk' classrooms. Therefore, schools complain Homo Zappiens to be hyperactive and not willing to listen for 40 to 50 minutes. Homo Zappiens feels uncomfortable not to be able to zap a talking head... and start learning. Current teaching materials and teaching methods are in conflict with the pupils' learning approaches.

Skills

BEST COPY AVAILABLE

But let's stop complaining Homo Zappiens and let's see what children have on offer for learning. By using the web for searching and communicating, by playing PC games, and by zapping TV channels, they have developed skills that are critical for learning. These skills are also critical in an information society in which it is no longer the content that matters but where the context is the core issue. Four skills are discerned and discussed below.

The first skill relates to scanning skills when Homo Zappiens deals with screens. Nowadays' children do not start reading characters when they are in front of a screen. Instead, they scan including colors, images, icons, symbols, movements and sounds. This approach makes them decide must faster where to go next and which button to press. This is the reason that parents always loose in competing to find information on the web. This skill makes kids efficient information seekers.

The second skill relates to multi tasking. Screenagers are able to do different tasks at a time. The screenager can be doing his math homework and communicating with a friend and at the same time finding some relevant information on the web. He is learning by active searching using technology as a tool. In our society, which is said to become more complex, individuals will have to deal with many different tasks at a time. Homo Zappiens is finding his way in advance.

The third skill is about processing discontinued information. Zapping TV channels is watching various interrupted information flows and making sense out of them. Notice that Homo Zappiens does not zap ad randomly, on the contrary, they have learnt to understand the principles of visual communication and consciously zap across the different channels. This skill helps kids to deal with huge amounts of information.

Many generations have been trained to read and study linearly. Homo Zappiens differs here again. He has learnt to look for solutions of problems at the appropriate time. When playing a PC game they do not start by reading the manual. They start by playing the game and only use the manual whenever needed. This is also the way students use books for learning. Web content by itself is organized in a non-linear way and it is the experience with this organization of information that they have internalized.

Learning

Do the skills and approaches of Homo Zappiens relate to learning? We think so. We learn by reflecting on our experiences creating 'mental maps' and 'mental models' (Bruner 1973). Learning is the process of adapting our mental maps and models by including new experiences. From a constructivist point of view, learning is searching for meaning. Individuals who learn try to transform new information in to meaningful knowledge. As a matter of fact, they construct knowledge.

Within the framework of complexity theory (Cilliers 1999) human brains are often discussed as examples of complex systems that are never in equilibrium, adaptive to continuous influences from the outside world, and self-organizing. They function in a highly non-linear way, building complex networks between neurons. Therefore, learning is a non-linear activity in nature (Robertson 2000 & Dennett 1998), in which association and creativity are crucial strategies. Homo Zappiens seems to have developed more natural strategies for learning.

Learning linearly, step by step has been a major pedagogical approach for decades. However, this is in contrast with the way Homo Zappiens is triggered for learning. He wants to be challenged by complex problems, which are presented in an authentic context, rather than isolated from real life situations. Learning should involve intense activities, including discussion, finding out on your own and using technology. Learning is an active mental process of the learner, which means that learning hardly occurs when students are listening somebody talking. Research has shown that the retention rate of lectures is around 5% only! The more active learning methods are, the more students learn. The learner himself can only do transforming information into meaningful knowledge. Therefore, teaching is facilitating students to learn. Churchill has put it this way: 'I do not like to be educated, but I like to learn.'

The skills and competencies that Homo Zappiens is developing are crucial for future citizens of the information and creative society.

We consider the screenagers' competencies crucial for the survival of our civilization in the 21st century. These competencies relate to strategies how to deal with information, how to process information, how to work together, and finally they relate to thinking. We need flexible individuals who are independent and self-directing and who are good thinkers.

Concluding Remarks

Teacher led learning has been widespread in education and training to date. It is the traditional teaching method of chalk and talk. However, as Homo Zappiens has developed the attitude to learn by himself he is very uncomfortable with this old pedagogical approach. Learner led approaches are much more appropriate for learners that have grown up in a technological society. Therefore, teachers will have entirely new roles to perform.

Independent learning cannot happen within the traditional sequence of out-of-office training days. A whole day of listening is a torture for Homo Zappiens and as we already know from educational research a very ineffective way of learning. Homo Zappiens should be able to learn *on-the-job* and *just-in-time* in *virtual learning and professional communities*. This means that human resource management has to change in the direction of e-learning. In addition to economical reasons for turning towards e-learning (e-learning costs about 50% of the traditional training) there seems to be another reason to adopt new ways to manage human resources. This reason relates to an upcoming labour force willing to learn and work differently.

Abstract: This panel session explores issues in relation to technologies and facilitation of community in the four key domains of the E-learn 2002 Conference, Health, Higher Education, Corporate and Government. While it is commonplace to say that people are the most important resource in organizations, we seldom understand this truism in terms of the communities in which individuals develop the capacity to create and share knowledge. These communities of practice are an organization's most versatile and dynamic knowledge resource. The panel presenters will demonstrate how in practice organisational learning can be supported through the marriage of online technologies and community development. Participants will have maximum opportunity to raise issues, both theoretical and practical, with the esteemed panel members in the discussion time devoted to this panel session. Follow these issues through the related Interactive, Roundtable and Special Interest Group sessions that accompany it in the Communities of Practice Strand.

Panel Chair: Etienne Wenger

CPSquare

Etienne is an independent thinker, researcher, consultant, author, and speaker, mostly known for his work on communities of practice. Theoretically, his work focuses on social learning systems. He is trying to understand the connection between knowledge, community, learning, and identity. The basic idea is that human knowing is fundamentally a social act. This simple observation has profound implications for the way we think of and attempt to support learning. Practically, these ideas are helping people who face all sorts of challenges, such as: design more effective knowledge-oriented organizations, create learning systems across organizations, improve education and lifelong learning, rethink the role of professional associations and design a world in which people can reach their full potential.

Communities of practice are emerging as the most promising structures for building knowledge-based organizations. They are the key to the knowledge strategy of a growing number of leading companies, government agencies, and non-profits. Community development is new to most organizations, however, and there is an urgent need for accelerated learning in this area.

The Communities of Practice

The Corporate Sector – *Clarica Agent Network*
Mary Lynn Benninger
Clarica, Canada

Mary Lynn is with Clarica, an innovative insurance company in Canada. Clarica was an insurance organization with approximately 3000 agents selling our products exclusively. As of December last year it was purchased by another large Canadian insurance organization and will have in the neighbourhood of 5000 agents. Communities will be a significant enabler during integration and moving forward.

During her 25 years with this company Mary Lynn has led teams, managed learning centers and end user departments. Her roots are in Information Technology. Five years ago she had an opportunity to work with Sr. Vice President of Strategic Capabilities, Hubert Saint-Onge. While working with Saint-Onge, Mary Lynn was responsible for the implementation of Clarica's Knowledge Strategy, leveraging web and groupware technologies. This included both Knowledge Access and Knowledge Exchange, focusing on the seamless integration of knowledge and e-learning.
Communities are the essence of the Knowledge Exchange work. The most important strategic community has been operational for 18 months now, and is called the Agent Network. Mary Lynn has a plethora of knowledge to share with us relating to the Agent Network; growth strategies beyond pilots, including keeping a community vibrant; the relationship between explicit and tacit knowledge and how communities fit into the bigger picture.

The Government Sector – *Change Management*
Panellist: Roy Greenhalgh
Consultant, UK

Roy is an independent consultant with over 30 years experience of designing and implementing IT systems in the private and public sector. As a Systems Thinker, he designs from the view-points of the end-user and encompassing end-to-end considerations. He has worked with some of the larger local authorities in the UK for over 15 years as the lead consultant in Public Sector division of IBM (UK). He has extensive experience of using Systems Thinking and process improvement tools in systems and process re-design.

Since becoming independent, he has worked with large local government authorities in developing and delivering major Change Management programmes designed to introduce middle and senior managers to current management techniques and skills. The programme also taught and enabled managers to understand how to design and manage improved processes within their own departments in line with the desire of UK government to deliver better value for money in public services.

His exposure to the problems of introducing IT systems and major change programmes has allowed him to study the informal CoPs that emerge in local government. A key part of any Change Management programme is to find the emerging CoPs and nurture them. They often form the key to turning an indifferent implementation into a successful one! All of the groups operate in local councils in the UK. Many are small, a group of 4 who facilitate the Help Desk for internal users of a council's IT system. Some are large crossing council boundaries. Typical is a CoP of administrative officers who administer Benefits. Not only do they share problems, expertise and skill amongst the physical group in each council office, but they also share expertise if the councils use, for example, the same proprietary software packages. The encouragement of such CoPs is a sensitive affair, requiring gentle tiller movements, and simply allowing members to get on with it.

The Higher Education Sector - *The Principals' Center*
Panellist: Thomas Ruhl
Lewis and Clark College Graduate School

Thomas Ruhl, Ph.D. is an Assistant Professor and department Chair of the Educational Administration Department of Lewis and Clark College Graduate School. He has served as a small school district superintendent, was an elementary school principal for 9 years and three years as a middle school administrator. He currently specializes in areas of school and district change, teacher supervision and program development.

The state of Oregon covers approximately 97000 square miles. Much of the area is sparsely populated with small communities made up of ranching, timber and agriculture families. Schools in these communities need to have leaders capable of leading small groups of teachers toward making continuous improvement in teaching and learning. The Principals' Center in at Lewis and Clark College is dedicated to helping principals in small communities become more effective leaders. One strategy being used to connect principals is through an online Community of Practice facilitated by an experienced principal serving as an adjunct faculty member of the Lewis Clark Graduate School of Education.

The Healthcare Sector - *Professional Education and Scientific Communication*
Céline Monette
Aventis Pharma

Céline Monette leads a scientific communication and a continuing health education group with a research section working on the integration and measurement of new information into practice of the healthcare professionals, and the transfer and management of knowledge. She also is working on the measurement of intellectual capital.

Céline Monette, director of Professional Education and Scientific Communication at *Aventis Pharma*, is also the co-chair of the Continuing Health Education Working Group of *Canada's Research-Based Pharmaceutical Companies*. She is actively involved in the development and implementation of Continuing Health Education as a discipline within the pharmaceutical industry.

Abstract: The sequencing of online course activities in higher education is a necessity to guide students through the course materials, discussions, etc. in learning environments where students and instructors are separated by time or space. Too often, online course management systems serve as basic course document retrieval and communication tools. Students then are left to navigate a course website haphazardly to determine a path through the wide array resources. This strategy for designing an online course interface at best subverts any instructional design for a course. At worst, it promotes the design of online courses that lack thoughtful consideration of the importance of the sequencing of course activities.

This paper describes efforts by the Idaho Virtual Campus to design a courseware research platform with a central organizing course feature that allows instructors to integrate all of the features of the course system and sequence activities into meaningful modules for online delivery.

Many authors suggest that online course systems should be designed based on educational theory (Huang, 2000; Ko and Rossen, 2001; Leflore, 2001; Smith and Dillon, 1999;). Leflore (2000) describes guidelines for Web-based instruction in three categories: Gestalt theory, cognitive theory, and constructivist theory. Of these three areas, the guidelines described for Gestalt and cognitive theory support the assertion that course activities need to be presented in an organized and meaningful manner. Leflore suggests that "when designing the layout of the computer screen, place related information together so that the learner will automatically group the information together as a unit rather than as separate elements." In designing a course interface, however, the problem arises of arranging items, such as courses readings, together with features of the course system, such as discussion boards. This problem becomes more difficult when using course management systems that are designed to separate course materials from interactive features like discussion boards and require students to move continually refer to a static syllabus or course schedule. This problem is addressed in IVC courses by designing a central organizing feature that allows instructors to group readings, discussions, online journals, assignments, and other items together in an outline form that groups and sequences these activities according to the instructor's design.

While a much of the relevant literature stresses the importance of planning and instructional design before building a web-based course. Instructors, however, are continually faced with either adjusting their instructional design to fit the course system available or creating a completely customized course website based on their design. Creating a customized course website allows the instructor complete control over the design of the course, but time, or a lack thereof, is often an obstacle for those designing web-based courses (Bonk, p. 14). In addition to time constraints, instructors are often faced with challenges of producing interactive and dynamic course websites that uses features such as discussion boards or online quizzes. Such features often require a high level of technical expertise beyond that of most instructors. Thus the problem becomes one of how to create a course system that can reduce the time needed to develop a web-based course and still allow the instructor flexibility to implement a quality instructional design.

The development of the course outline feature faculty was done primarily by designers who had taught, taken, and designed online courses for several years and also involved many other instructors at several institutions who would be using the course system. This development was guided primarily by the desired functionality and instructional principles and then was examined from a web design perspective. Three requirements emerged: (1) a central organizing feature must be able to incorporate all other course features available, (2) it must be allow instructors to organize information according to varying instructional designs, and (3) it must be simple enough to allow for easy organization and modification of material and activities as a course progresses and is revised.

The result of this collaboration was a dynamic course outline feature designed for the IVC which enables instructors to integrate all other features of the IVC course system (i.e. discussions, course library, online journals, etc.) into a single interface for the students. Instructors build the course outline dynamically via web based forms and are capably of organizing readings, discussions, required journal entries, assignments, quizzes, etc.

The course outline feature also allows instructors to set a date range for particular sections of the course outline. Those sections are then displayed when a student enters the course on the main course web page that displays current course information.

While there is no single solution to address all of the needs of distance education, it is clear that a course management system should enable and promote quality course design and also that this design should be firmly rooted in sound educational theory. The course outline feature of the IVC course system is an emerging solution that has been developed with these educational theories in mind and also the needs of the instructors who are designing and teaching web-based courses. The ability to organize and sequence course materials and activities into a single and clearly presented interface provides the means by which quality instructional design can be promoted and enabled while also providing stable and useful course tools to the instructor and student.

Classroom Observations through Distance Learning Technology

Phyllis K. Adcock, Ph.D.
Department of Teacher Education
University of Nebraska at Omaha
United States
padcock@mail.unomaha.edu

Abstract: The purpose of this paper is to share how integration of distance education technology, in teacher preparation classes, provides an alternative observation method of school classrooms. A study was conducted in Human Growth and Learning classes at the University of Nebraska in Omaha, which practice both traditional on-site and alternative remote observations in schools. These observations are completed for the preschool, kindergarten, special education, elementary and secondary levels. It has been found that those levels which offer the most interaction between teacher and students in the preschool, kindergarten, and special education classrooms, work best with the alternative remote observation method. The traditional on-site visits by university students are conducted for the elementary and secondary levels, where there is less interaction. The findings indicate that both observational methods provide good experiences for university students.

Introduction

Many teacher preparation programs have teacher candidates in classroom on-site visits in every year of the college experience (Darling-Hammond, 1998). When one considers the time involved, the liability issues of on-site visits, and safety management of schools, as well as the intrusive nature of on-site observation visits, it is possible that those visits could be limited, therefore alternative methods may be needed. Technology can provide alternative observation methods through a two-way audio/video conferencing system, providing remote observations at school sites. This type of alternative observation method is being employed at the University of Nebraska at Omaha (UNO), by conducting part of the required observations through this form of distance learning.

Alternative Observation Technology System

At the University of Nebraska at Omaha, federal funding was secured for a two-way audio/video conferencing system. A two-way conferencing connection is possible through a computer's internet protocol (IP) number that allows remote viewing of any classroom with ethernet connections to the internet. A port in the firewall, which block incoming and outgoing electronic traffic, must be opened at each site to allow for the two-way connection. A T1 line of a high bandwidth is preferred to handle the high traffic these audio/video connections generate. Keep in mind it is the amount of internet traffic an institution has that can make a difference, especially in the video display.

This conferencing system allows for two-dimensional viewing of the classroom through a camera which is about 8 inches high and 4 inches wide and is virtually soundless. The microphones are placed strategically around the room to pick up the voices of the teacher and the children. At the university, the students have the ability to view the remote classroom on a large screen. The university students can make suggestions of what they would like the camera to focus on, because the camera is controlled from the classroom on campus. Therefore the alternative remote observation method can easily follow the learning activity, such as when the teacher is in a large group setting, or zooming in on small group activities.

If an interactive approach is desired, the video display allows for viewing of both classrooms simultaneously with the picture-within-a-picture option. The remote video observation can be taped, which gives the university classes flexibility for viewing during class, or at a later time for example, with evening classes. This taping feature is also helpful with children's classroom schedules which do not provide quality observation time, such as when a child is engaged in quiet reading time, or when children are away from the classroom for lunch and other activities. This conferencing system is similar to other forms of distance education technology that is being used at a few other universities (Olafson and Quinn, 2002).

The Study

In the Human Growth and Learning class (EDUC 2010) at UNO, university students have five observation experiences at the preschool, kindergarten, special education, elementary and secondary levels, which are guided by field competencies. Through these observation experiences, university students can gain an understanding of how children learn, in what type of setting (Darling-Hammond, 1998), and how children differ in physical, intellect and language, and psychosocial development (Flavell, 1993).

From the pilot experiences of integrating this technology into classroom observations, several valuable lessons have been learned. It was determined that the best classroom observations, using technology, occur when there is more interaction between the teacher and the children. Situations which involve younger children, or children with special needs require more interaction on the teacher's part. As a result of this discovery, the remote audio/video observations are scheduled at the preschool, kindergarten, and the special education levels. The traditional on-site visits are scheduled at the elementary and secondary levels where there is less interaction between teacher and students.

A qualitative study was completed, during the fall 2001 and the spring 2002 semesters, involving randomly selected university students who had the alternative remote and the traditional on-site observation experiences. These students were asked the to compare and contrast both observation experiences. In their comparison, the university students were to consider the physical setting of the classroom, the nature of the instruction between the teacher and the children, and the development of an individual child in the physical, cognitive, and psychosocial domains.

Summary

A comparison of the responses of university students who completed both classroom observation methods was conducted. By using the field observation competencies as a guide, the surveys were assessed for the difference in student responses to the two forms of observation methods.

What was found in these surveys was that even though the camera could pan the classroom and zoom in on learning activity, the entire classroom could not be viewed at one time. Students also stated that it was easy to follow the teacher-student interaction, but when it came to focusing on one child's developmental observation it was more difficult, unless the student was in camera range for an extended period of time. The surveys revealed that at times it was difficult to determine who was speaking when the camera shifted away from the speaker to other activities.

Finally, university students stated that the remote observation was convenient and they were impressed with the quality of audio/video output. The students describe the audio as being very clear, and the video was clear enough they felt they were having a 'real' experience.

Conclusions

Considering the observation experiences and the university student comments on the surveys, it has been concluded that both methods of observations provided the university students with good observation experiences for an introductory class. Also, the remote observation experiences work best with the younger and special needs child, due to the greater opportunity for interaction in the classroom with other students. Finally, students claim the remote observation were no more intrusive to the school classroom than the traditional on-site visits. Some of the students thought the remote observations visits were possibly less intrusive, because many of the children forgot about the camera in a few minutes, but continually gave attention to the visiting university students in their class during the on-site observation experiences.

With the continued success of this alternative observation method through the conferencing system, colleges and universities can provide quality observational experiences by integrating distance learning technology into teacher preparation program classes (Christopherson, 1997).

Acknowledgements

The research and this paper on alternative classroom observation through a two-way audio/video conferencing system was made possible by a grant awarded through the Preparing Teachers to Teach with Technology Program (PT3), of the U.S. Department of Education and the funding provided by the Nebraska Partnership for Quality Teacher Education grant. Many industrious administrators, faculty, and staff from the University of Nebraska at Omaha, such as Dr. John Langan, Mrs. Becky Schnabel,, Dr.Neal Topp, Mr. Bob Goeman, and Mr. Paul Clark, to name just a few, have provided the ground work and continued support for the success of the alternative observations for the Human Growth and Learning classes.

Automating Evaluation and Assessment in a Technology Course

Frank Akaiwa
Operations and Decision Technologies Department
Kelley School of Business
Indiana University
United States of America
fakaiwa@indiana.edu

Bill Littlefield
Operations and Decision Technologies Department
Kelley School of Business
Indiana University
United States of America
littlefi@indiana.edu

Abstract: This paper is a report on efforts to use technology to improve and maintain consistent student evaluation and assessment in two large technology courses at Indiana University. One difficulty in managing large courses is maintaining quality and consistency across all sections. Staff members of these courses have developed a web-based course infrastructure and an automated grading system to help with this problem. The web-based system runs on a UNIX server with pages generated in PHP, using a MySQL back-end database. In conjunction with other components of the course, these automated systems reduce the burden of student evaluation placed on instructors and improve consistency. The development of these systems and the results will be discussed.

Background

Students at the Kelley School of Business are required to take two introductory technology courses. These courses are informally thought of as a technology foundation. The first course, *K201 The Computer in Business*, requires all undergraduate students to demonstrate proficiency in working with spreadsheet and database application software, and demonstrate a basic understanding of the importance of information systems technology in business. This course or its equivalent must be taken to apply for admission into the Kelley School. Since this course is often the student's first contact with the Kelley School, a key aim is for the experience to be consistent for all students. From an admissions perspective a critical goal is to ensure that student grades are consistent and not inflated across sections for a semester or between semesters. The second course, *X201 Technology*, requires students to apply many of their K201 skills to more abstract, less structured examples. Thus the emphasis is much more on analytical skills rather than problem solving skills. Students work individually and in teams on a business case throughout the semester to increase their spreadsheet and database skills, learn spreadsheet-based simulation, and develop an understanding of how technology is adopted in business.

An increasing number of students have been enrolling in K201, placing significant pressure on resources and the quality of teaching. Six years ago K201 was comprised of thirty-two sections per year. This year we will offer and fill over one hundred sections. The demand for this course is substantial. Prospective business students, as well as students from other schools within the university, pushed enrollment above 1,700 students for the Fall 2001 semester. This level of enrollment requires 56 lab sections and seven lecture sections, using 36 instructors and more than 150 other support personnel. This steady increase in demand has required increasing attention to course administration; instructor training and evaluation; and the leveraging of information technology to continue to bring students a measurable, high-quality instructional product. We have been innovative in our strategies for administration and teaching.

A key example of innovation is the course web site and its attendant support system. The web site provides students with access to course information and resources; distributes assignment, lab and tutorial files used in the course; and is the tool used to coordinate access to help and support for students. The system is also designed to allow students to submit their assignments for grading through the site. This submission component is combined with an automated grading system to minimize discrepancies in the evaluation of student assignments.

Because both full-time faculty and part-time instructors are used to deliver course materials, the level of knowledge, experience, and commitment to the course by the instructors is quite diverse. While some instructors have years of experience teaching in technology courses, a large group of the instructors are MBA students assigned to teach in the course as part of their Graduate Assistantship. A comprehensive set of materials is provided to all instructors including teaching outlines and files. These files are composed of before-class exercises, in-class examples, and post-class assignments. These materials allow new instructors to present a technically demanding course in the same manner as more experienced instructors. Automated grading is the cornerstone of uniformity in the course. The goal is to reduce the subjectivity found in grading assignments and problem-based exams by using Visual Basic for Applications to grade file properties for Excel and Access assignments. The result is an online submission and automated grading system that is described below.

Description of System

The web-based system currently runs on a UNIX server with pages generated in PHP. The back-end database is MySQL. The dynamic web site captures the username of the person visiting the site and customizes the website to their individual section of the course. The website displays the current week's lecture and lab topics, assignments, links to web articles, and files used in that week's exercises.

Students submit graded projects throughout the semester. Projects are set up as problem solving exercises using varying levels of structure. Projects are available one week before they are due, and are downloaded from the website by the student. Projects for the first half of the semester have built in feedback to help students learn how to error check their assignment before submission. Later projects lack this pre-submission feedback mechanism. The student's username is captured to the graded project when the student opens the file for the first time. Students do not have access to the location where this information is stored, thus they cannot change the username that has been captured. This username is used later in the grading process. After completing the project, students submit it to the course web server, using the link supplied on the web site. Project submission deadlines are based on the time that class begins for each section on the day projects are due. For example: *the student has lab at 8:00 am on Monday and Wednesday, and the project is due that Wednesday by the beginning of class. At 8:01 am, the student will not be allowed to submit their project online.* The system captures the username of the person submitting the file and adds it to the filename. This keeps students from having someone in a different section submit their project for them. The student's username that was captured when they began work on their graded project or exam is compared to the username of the student submitting the project. If the usernames differ, an investigation for academic misconduct is triggered.

Lab exams or practical exams take a similar form as graded projects. Students are given two hours per exam to solve a set of problems in Excel and Access. Exams are given on weekends at mid-term and the weekend before finals in a five-round format. This places a significant demand on the campus' computing infrastructure. The exam is coordinated between the fifteen exam sites by use of a bulletin board on the instructors' website. This enables constant communication between all proctors and the exam coordinator. This communication is critical when uniformly solving problems that may be encountered during the exam. The lab exams are structured to test the student's understanding of the tool and its application to solving a problem. The automated grading system allows us to build multiple versions of the exam into the same Excel file based upon the version of the exam. The version of the exam the student takes is determined when the student opens the file and enters their name and section number.

Once the files have been submitted, the system places the files in a subdirectory on the server based on the student's section. After all projects have been submitted, the files are released to the section's instructor for grading. The grading process is fully automated. Using Visual Basic for Applications in both Excel and Access, the cells in the spreadsheet and the records in the database are evaluated for a number of different properties. The grading system is composed of an Access database and separate modules developed in Access and Excel designed to grade each of the projects and lab exams. The system is designed to provide individual student performance as well as performance by lab section. The system does not capture keystrokes; it focuses on the methods that were used to find the answer and the correctness of the answer. The average grading time for an instructor with 40 students in a section is less than ten minutes per project. Evaluation of student trends is available to both the lab instructor and the course coordinator. This allows an analysis of teaching outcomes both within a section and across sections.

Following the submission and grading of student projects and exams, the website is used to post student grades. Students have two weeks from the time grades are posted to protest any inaccuracy in their grade. Since the lecture and lab components are taught by different instructors, the centralized posting site allows grades for both components of the course to be joined to provide students with an accurate report of their grades.

Results

The system has allowed K201 to significantly increase the number of sections taught while maintaining quality and consistency. The website enables the efficient distribution of course material, the submission of student work from any location with access to the Internet, and the delivery of detailed student feedback. The automated grading system allows K201 to use more rigorous and realistic assignments than would be possible with manual grading. A side benefit is that instructors get to spend more time teaching and answering student questions. The data collected by the grading system is also used to monitor course quality. Grades can be compared by section and topic at both a summary and detailed level. This information can indicate problems with sections, instructors or teaching materials. The system allows the course coordinator to identify possible weaknesses with lab instructors and work with them to improve their teaching. In the case where a particular topic area has a low average across all sections, instructors evaluate the assignment to determine if it is flawed, or if the teaching materials require revision.

The systems described above are being extended into X201, the next course in the technology foundation. Many of the same benefits have resulted, but differences in the courses have led to difficulties with automated grading. X201 is a much less structured course by design. In an effort to provide a realistic and relevant learning experience, students are given much more freedom to design their submissions for course assignments. The subjective nature of grading in X201 requires more manual grading of student assignments. The grading system has been altered to provide more grading assistance than automation for many assignments.

Conclusion

Overall, the online system has been extremely successful for K201. It is continually being modified to improve the learning experience for both instructors and students. The online system is mostly meeting the needs of X201. The difficulty of scaling the system across two large courses along with differences in the degree of structure for these courses has led to a separation of system development efforts. Nevertheless, the same principles are being used to guide on-going development for both courses. Both courses require an infrastructure that enables the delivery of content that is rigorous, realistic and relevant to the student. This results in assignments that are fairly complex and difficult to grade. This infrastructure must maximize the time an instructor has to teach and respond to student questions.

EFFECT OF LANGUAGE ON E-LEARNING IN THE ARAB WORLD

Abstract

Language is an important aspect of communication which is the only means of interactions in learning. Electronic-learning (E-learning), being a form of a virtual teacher, pseudo-teacher or complementary teacher is characterized with students' interactions. The study of language reveals its importance, whether as first, second or tenth and these are crucial in the conduct of e-learning especially in the Arab world. Language has significant roles in the way in which learning occurs and consequently, the success or failure of e-learning in higher education systems where English is not the first language. The Arab world is conscious of its importance and steps are being taken to face the challenge.

Introduction

The human mind is so difficult and complex to understand. Research in this field must be taken as an on-going process in order to unravel the mystery. While no psychologist has been able to pinpoint exactly when a learner, in a learning situation actually commences to attend to the learning stimuli presented, it remains the duty of a teacher to create a conducive atmosphere and environment and for the stimuli not only to turn the learner on, but also to maintain and sustain attention through out the learning session. Further, attention is drawn to two models, which are of vital importance in school learning. The information processing and communications models reveal the attributes of a learner (internal processes) and his/her environment (external factors) and those barriers and impeding forces that can inhibit learning.

In order to get to grips with the theme and focus of this paper, there is need to understand some related terms in this discourse. These include – Learning, e-learning, the e-learner, language, communication, and the significance of instructional design in e-learning as these all relate to experiences in the Arab world.

Learning and Education

Learning is the essence of education and the literature is replete with definitions, meanings and the complexities of this subject. The Oxford Advanced Learner's Dictionary defines learning as 'knowledge that you get from reading and studying' (Wehmeier, 2000). It suffices also to state that learning is a change in disposition which is not attributable to growth or maturity and which can be retained over time. In order for change to occur in the behavior of a learner, it will do so as a result of a stimulus or stimuli impinging on the learner. The impact of the stimuli must be meaningful, strong, and capable of making the desired change to occur within a short time. Stimuli come in various forms and configurations. These are usually communicated in any or a combination of the following ways - symbolic, verbal, spoken, written and nonverbal in the form of body language.

Learning is known to result from an interaction of symbolic experiences, which may be verbal or non-verbal cues. These are extensively used as means of communication in education. Learning also occurs through vicarious and direct experiences. It is essential to stress the importance of visual literacy in teaching and learning. Visual literacy is the ability of an individual to interpret accurately, visual messages and make applications of them in learning.

In the process of learning, the five major senses involved include seeing, hearing, feeling, smelling and tasting. Of these, seeing and hearing have been found through research (audiovisual) to dominate the learning scene. For example, there is an overwhelming evidence that about 83% of learning occurs through seeing, 11% through hearing, and only about 6% through the senses of feeling, smelling and tasting when added together. Further, evidences have been provided in the literature that retention from sight and sound stimuli is estimated to be 50%. Comprehension has been reported as 15% through hearing and 40% through seeing while the combination of both is estimated to be about 70%. All of these evidences underscore the fact that learning occurs through the multi-sensory approach. It is important to state that individuals who are handicapped partially or totally in any of these two most important senses (the blind and the deaf) can and do learn as their other senses have been known to compensate for the handicap(s) in one way or another. This is, however, beyond the scope of this paper.

The effect of the use of multiple senses affect e-learning since the learner must interact with resources. Direct experience, which involves the use of more than one of these senses, gives an individual the responsibility for learning outcome. The Internet which is central to e-learning has most of its resources in English language and this underscores the need for accelerated attempt to convert materials into Arabic or offer courses in English language, if only to benefit from the rich resources on the Internet.

E-learning refers to the use of the Internet technologies to deliver a broad array of solutions that enhance knowledge and performance. E-learning has been reported to be based on three fundamental criteria:

- E-learning is networked, which makes it capable of instant updating, storage, retrieval, distribution and sharing of instruction or information.
- It is delivered to the end user via a computer using standard Internet technology.
- It focuses on the broadest view of learning – learning solutions that go beyond the traditional paradigms of training.

(Rosenberg, 2001, p.28).

The e-learner can then be described, from the foregoing as the individual who interacts with the resource materials for e-learning with the purpose of acquiring knowledge and information. The nature of e-learning makes it possible to tagged 'an any time, anywhere' learning mode. Let us now consider the language factor in learning and in e-learning..

Language Factor in Learning

Language is a unique and powerful means of communication. It may be verbal or nonverbal and it occurs in both living and non-living things. Inanimate objects do communicate as well. They react and respond to stimuli around them. The sunflower for example, responds to sunrise by turning to the direction of sun rise. The stem of the yam root tuber and similar plants like this will twist around their stakes in response to the order of the farmer. In other words, inanimate objects can also be said to respond to human communication!

It is language that makes us human and enables us to work together in all activities of life. It is a rich, varied and very flexible instrument, which plays a major part in our daily activities as well as in teaching and learning, regardless of the region of the world we are in. Though distances separate individuals, language and communication can bridge the gaps in feelings, thought, intentions and plans as ideas can easily be articulated. The importance of language is underscored in the statement that 'the mastery of the word is the mastery of the world'. Word power is indeed magical and language (verbal and nonverbal) remains the most important factor in communication. This is the essence of the focus of this paper on the effect of language on e-learning. Kelliny (2002) reports the dominance of English as the Internet language of choice. Language can make or mar an e-learning system if due attention is not given to its form and structure in the design of Web materials. This is not only with regards to the Arab world but also other educational systems where English is not the first language.

Kelliny (2002) states that the first challenge in the use of the Internet is the working knowledge of English Language for the non-English speaking world as English is the universal language of communication, information technology (IT), business, technology, industry, advertising, entertainment and leisure. In the Arab world, the Arabic language is used in most of the communication activities. In the context of Kelliny, the Arabs might be some how disadvantaged in that those who are not literate in English, cannot benefit from the wealth of available information which are predominantly in English.

Communication in Learning

Communication is the activity or process of expressing ideas and feelings or of giving people information. Effective communication is the key to reaching the highest level of learning. This is particularly important in e-learning where the teacher may be 'virtual' not real. Even in ordinary conversations, when communication breaks down, we feel helpless, frustrated, angry and mystified. The importance of language in e-learning cannot be overstated in view of the high degree if interactions with the resources.

Communication is a two-way process between the source (teacher/e-teacher) and the destination (learner/e-learner). The process is not complete without the inclusion of the message/e-message, channel of information flow (virtual), feedback/e-feedback and possible sources of noise/e-noise, which may render communication ineffective. Between the source and the destination are the critical activities of coding, encoding and decoding. The teacher must be able to code and encode information, the coded information must be relayed to the learner and the learner has to be able to decode information so transmitted. As a complement of the available communications model, there is the information-processing model (Gagne et al, 1992) which explains what is involved, when the information is received from the learning environment by the learner, to the time when the response generated by the learner is given back to the environment in writing, action or both. The importance of language and communication in any learning setup are issues which educators are interested in so as to maximize learning.

In the Web-based parlance, there are two main types of communication modes. The asynchronous and synchronous communications characterize much of e-learning approaches and there are combinations of these as well. Asynchronous delivery refers to programs that are independent of time as in the case of prerecorded audio, video and CD materials being used in e-learning. In this case anyone can access the program at any time and as many times as desired. There is no live component and it may not involve strict scheduling. Communication between people does not take place in real time. Synchronous approach refers to programs which are time dependent, where communication takes place in real time as in 'chats' and 'video conferencing'. Delivery is live and once a learner misses it, that would have been the end except the program is repeated or recorded for later viewing. Whichever approach is adopted, the language component remains an important determinant of its ability to effect learning only when the learner is literate in English language.

Instructional Design and E-learning

Text presentation and density are very important in e-learning. The Arab higher education institution have long recognized the role of instructional design (Educational Technology) in teaching and learning and virtually all Colleges of Education in universities and teacher colleges have programs or courses in this new discipline. Our concern in this paper will not extend to issues of text characteristics, text formatting, and text density on the monitor as well as the screen density of texts. However, research in the area of text density has suggested that low density text is a viable technique for presentation of lengthy text materials (Berry, 2000) and also that text should be presented on Web pages in short chunks and should be edited to simplify content (Nielson, 1997).

The factor of instructional design in e-learning is an important and complex activity as even the language expert will need to be guided in making a success out of the web design venture. Many models exist in the systematic design of instructional materials, which can also be applied in e-learning (Heinick et al, 1999, ASSURE model; Gagne et al, 1992; Dick and Carey, 1990, Systems Approach model). No particular model is a panacea, however, it is necessary to design a suitable and convenient model (hybrid) for the Regional e-learning practice where the Internet materials and resources are to be converted from English language to Arabic or other languages. The evaluation and revision phases of any model, if properly executed, will eliminate language anomalies in the e-learning system.

Berry (2000) indicates that the World Wide Web (WWW) is essentially a visual medium and that designers should rely primarily on visual displays to communicate their message while at the same time de-emphasizing lengthy text passages (Berry, 2000, p.48). If the concern for text density and page overload are not detected and adjusted at the design stage, the whole e-learning design exercise will be ineffective. Berge et al (2000), further prescribes some vital elements in the design of Web-based courses.

Language effect on e-learning is far from being restricted to programming languages. The emphasis here is on communication and learning through the tools of interaction either with the e-teacher (Web materials) or with the others in the learning community through synchronous/asynchronous communications. Language, whether as first, second or tenth is the tool of interaction on the Web and as earlier indicated, it may be as symbols, verbal or non-verbal. Language defects and problems are easily identified and rectified at the formative stages of the design phase rather than at the implementation stages

Conclusion

Learning, language and communication constitute an intricate web in education. They are inseparable ingredients in e-learning. Courseware designers and instructional developers must integrate them as they apply the system approach principles in designing materials for effective education. The language used in e-learning courses must be of high standards to promote virtual learning. Communication techniques and the technological set up must be user-friendly as not to leave the learners frustrated and mystified through the use of inappropriate feedback and reinforcement principles.

The language used in the text must be according to the level for which it is prescribed and of appropriate vocabulary level. The use of technical terminologies must be carefully explained and the text density must be such that will not overload the e-learner. Sentence complexity must match the level of the learners for which material was designed. Concern for language is perhaps most fundamental in a successful e-learning system as well as all training and other educational endeavors. Finally, e-learning has been coined by Al Balooshi (2001) as the 'now big thing' and not the 'next big thing' in the Arab world as well as in other parts of the world (developed and developing). This is further endorsed by the words of Canning-Wilson for the language teachers in the Arab world. Teachers of other school subjects must also take a cue from this warning:

> "Soon the on-line language teacher will replace the EFL/ESL classroom teacher.....Those trapped in the world of the chalkboard and textbooks may be left behind as education advances into the 21st Century" (Canning-Wilson, 2000).

Abstract

The adoption of Web-CT marks the beginning of a new era of instructional delivery mode at the Sultan Qaboos University (SQU). Increase in faculty interest in the use of e-learning marks a significant evidence of technology infusion into higher education. Faculty members from colleges have registered substantial participation in various training programs of the Center for Educational Technology (CET) with a view to utilizing this technology in teaching. The challenges of the new technologies are being surmounted. Solutions which encourage faculty utilization of technology are being proffered and these will also promote a lasting integration of technology into teaching and learning in the Sultanate of Oman.

Background

Traditional education can no longer cope with the modern teaching and learning requirements. Cunning-Wilson (2001) warns that soon the on-line language teacher will replace the EFL/ESL classroom teacher and that those still trapped in the world of the chalkboard and textbooks may be left behind as education advances into the 21st Century.

The rate of technology and information explosion calls for the use of appropriate technology to cope with the contemporary education practice. In order to improve teaching and learning and improve the services of the CET, cutting edge technology equipment were acquired. E-learning had long been talked about but never seriously pursued in SQU. The CET took a bold step of studying many of the available e-learning programs (Blackboard, Learning Space, Web-CT and others) for their infrastructural needs, ease of operation, effectiveness and efficiency and then recommended the Web-CT to the University. The University acquired this program, being the most widely used in higher education, after satisfying the criteria for selection.

Web-CT Adoption

The Web-CT vendors were invited to make presentations and run a workshop to familiarize the potential users (Faculty members) with the rubrics of the new program.

The CET set up the machinery for running the program for the first time in the Fall semester with nine early adopters from four colleges and in nine courses. The implementation and perspectives of the early adopters have been reported in Akinyemi et al. (2001). In order to properly install he new program and explore the full benefits of e-learning, a special meeting was convened with the early adopters to obtain information on their perspectives and implementation related issues. Deliberations at the meeting brought out many substantial information which contributed to the improvement in running Web-CT with the second batch of adopters in the Spring Semester.

Expanding the Scope of E-Learning

In order to intimate faculty with the availability, value and use of the new e-learning package, awareness presentations were made on a college by college basis. A Web-CT help-desk was formerly established and necessary assistance is given to faculty on student registration. Two workshop sessions were run for interested faculty members on the Web-CT rubrics. Workshop contents were basically the program features and the management of students and courses. The University is working on improving the infrastructures and increasing the numbers of computer units and laboratories for Web-CT utilization. The logistics for increasing the opening hours of computer laboratories and the institutionalization of dedicated times for Web-CT are being considered to make e-learning a worthwhile experience in SQU.

CET has collaborated with the College of Medicine in putting one of its learning segments – Case-based Respiratory System on the Web-CT. The new design is currently being run on an experimental basis. It is hoped that other segments will be put on the Web as soon as the present study proves successful. Other colleges are considering going online with some of their courses as well.

Challenges and Issues

Innovations are usually never effected without some teething problems. Change is not easy to effect in any system, especially with human beings (faculty) and this is perhaps why it is often said that "you cannot teach an old dog a new trick". People will ordinarily resist change especially if it is, at a cost. Putting a course on the Web-CT requires a substantial amount of time and effort on the part of faculty. This was the essence of the faculty awareness presentations and workshop series being embarked upon by CET. The faculty attendance and participation at the presentations and workshops provide a comfortable feeling of interest and willingness to embrace the new technology.

In the course of running the Web-CT we have faced some challenges such as student difficulties in accessing the server, inadequacy of computer units, faculty computer inadequacy, need to increase bandwidth/infra-structural capacity, and the need for online helpdesk. These are just a few of the challenges facing this new technology. Measures are being taken to provide solutions to these challenges and issues on a short and long term basis. A new Web-CT Vista version, which is supposed to be more versatile and easier to run, will perhaps encourage more lecturers to go online. The University is considering purchasing the new Vista version in due course.

Conclusions

Technology infusion into higher education in Sultan Qaboos University is becoming a reality. The spill-over effect of e-learning will positively affect the entire Sultanate of Oman as technological literacy permeates the learning processes across the colleges.

Teacher education programs will produce teachers who are technologically competent as opposed to the traditional education system which produced teachers who are prone to technophobia. The positive attitude of faculty across programs towards e-learning as demonstrated through their willing attendance of presentations and workshops is a reliable proof of interest in technology adoption. The increasing trends of faculty adopters of the Web-CT are adequate justifications for the reality of e-learning in higher education in the Sultanate of Oman.

Technology and Pedagogy
Changing Roles of Pedagogy in a Project-based Constructivist Environment

Ahmed Ali and Dr. Teresa Franklin
Ohio University

Introduction

Educational institutions are reassessing the instructional approaches that have been commonly used in the past, when traditional, teacher-directed instruction was widespread. There have been calls for the need to develop students who are critical thinkers, independent and innovative. Unlike before, when teachers had been deemed the keepers of knowledge and "sages on the stages" (Rield, 1995), advocates of change have focused on utilizing designs that engage students and make them part of the teaching and learning process. In line with this approach, the following have lately been increasingly practiced: discovery learning, problem-based learning, project-based learning, individualized learning, collaborative and interactive learning, and one-on-one mentoring. The common denominator of all the aforementioned strategies is that they are student-centered. In embracing this approach, technology inevitably becomes a viable tool to use.

The site of the study, the Global Learning Center (GLC), was a project-based, student-centered learning program started 2 years ago at a Midwestern University. The program prepared students for leadership opportunities in a rapidly changing world. Open to all majors, the GLC brought together the resources of three of the university's top-performing colleges-Business, Communication, and Arts and Sciences-in an interdisciplinary, 30quarter-hour undergraduate certificate program on global issues, with a strong emphasis on real-world projects and problem- solving skills. This was a learning and living program in which students lived as a community in one residential building. Courses were not traditional classes with lectures, tests, and papers. Instead, students worked in project teams on real-world problems and issues.

Technology's use in the program was underscored by the emphasis on use of the Internet for administrative and instructional activities; every student was given a laptop computer with several different software applications loaded to facilitate student coordination in working on projects, and there was a well-equipped computer lab for the students. Students used electronic database for discussions about their group activities and for dialogue with teachers. Teachers used the database to guide students during their work on projects, and also used it as a forum for other instructional activities with either students or colleagues. The lab had PCs and Apple Macintosh computers, printers, scanners and other accessories. The students had access to the lab 24-hours a day. Rooms used as classrooms had television and VCR, LCD projectors, and laptop computers that students used for presentations and discussions, and teachers used in their teaching. With the widespread use and promotion of technology in the program, we examined the role of technology in project-based learning by seeking answers to the following questions:

1. Does the use of technology impact project-based group work by students?
2. Does technology support the mentoring of students in a project-based learning environment?
3. Do the technology-rich methods for content delivery support the implementation of a project-based learning environment?
4. How do students and faculty perceive the role of technology in supporting the pedagogy of a project-based learning environment?

Changing Teaching and Learning Environments

Newby, Stepich, Lehman, & Russell (2000) contended that changing instructional environments in schools has necessitated a change in the instructional styles. Newby et al. argued, unlike in traditional settings, today's graduates are required to possess skills in problem solving, stating, "Learners must now be viewed as proactive participants in learning, actively seeking ways to analyze, question, interpret and understand their ever-changing environment" (p. 6). Newby et al. asserted that students in today's classrooms are diverse, coming from different backgrounds, with different learning styles and interests, and thus there is need to accommodate individual concerns. They noted that information technology had a great impact on learning, leading strongly towards learner-centered instruction.

Project-based learning is based upon students working on real-world problems with the aim of finding solutions to the problem. Every individual has the potential to find the solution. Kozma & Shank (1998) argued the nature of this approach creates complexities for students and teachers and suggested that technology is an important tool that can be used to facilitate this complexity.

Working on projects is an important strategy for obtaining skills through practice. But working on real-world projects in today's classroom setting is not easy. There is the danger of students focusing on completing the project rather than the learning goals of the project and learning process (Guzdial, 1998). According to Guzdial, while technology may not successfully lead to successful project-based learning practices, it can reduce costs, improve learning, and make project-based learning more practical.

Project-based learning is helpful to the intellectual, social, and emotional development of students. Teachers contribute more actively to the intellectual and social development of their students in a project-based learning setting. Experience in the challenging tasks of a real-world problem improves student's readiness and ability to deal with complex issues within and outside school as they grow. However, not all students and teachers benefit from this approach. Its use should take into consideration the needs of students, teacher preference and skills in the use of this approach, and what is being taught (Katz & Chard, 2000).

Peer Learning

Workingin groups creates a sense of community, where students feel responsible for some of activities that encompass the group. They work together, work out individual differences and disagreements, and participate in decision-making.

In review of research, Sandholtz, Ringstaff & Dwyer (1997) reported that peer learning increases student learning, increases student self-esteem, and is a motivator for students. A study by Sandholtz et al. (1997) on the Apple Classroom of Tomorrow Project, ACOT, project discovered that peer learning made learning personal as students assisted each other on a one-on-one basis, which improved students learning, self-efficacy, and academic achievement.

BEST COPY AVAILABLE

According to Maier & Warren (2000), working in online groups gives students and teachers flexibility in learning and teaching compared to traditional, classroom instruction with fixed schedules and content. They added that the online environment creates more discussions and encourages teachers and students to share their experiences and knowledge. They asserted students have more control over their learning, leading towards a more student-centered learning.

Technology

In an evaluation of the ACOT, Sandholtz et al. (1997) discovered that technology played a major role in changing the instructional style from teacher-centered to student-centered. According to Sandholtz, et al. (1997), "Technology is a catalyst for change in classroom processes because it provides a distinct departure, a change in context that suggests alternative ways of operating. It can drive a shift from traditional instructional approach toward a more eclectic set of learning activities that include knowledge-building situations for students." (p. 48)

Technology has changed the way students learn in schools. Students are no longer expected to learn specific sets of knowledge or skills. Unlike before, when content and subject matter was made and decided for students, today's students have various tools, notably technology, that they can use under the guidance of the teachers (Maier, et, al., 1998).

Technology empowers students. It provides students with opportunities to work on problems in order to provide solutions. It enables students to share their skills and abilities with their colleagues, teachers, and other community members. Technology can make students work on projects that would be difficult to work on without it (Moursund, 1999).

Technology can be detrimental to learning if it is introduced without careful instructional design. The benefits of technology may not be realized if appropriate design and teacher's skills do not precede introduction of technology. "It is the pedagogy, not the technology, that is the key.... It's a mistake to put technology center-stage as we plan and execute educational reforms. Technology should hover shyly in the wings, ready to lend its power out only as needed" (Brackett, 1998, p. 30).

Field work

One-on-one interviews with 20 participants were conducted to gather information concerning the impact of technology in project-based learning (PBL). The PBL involved students working in groups to design and implement projects. The majority of our interviewees (15) were students who used technology for their learning in a variety of ways. While current students provided information about their continuing experiences in using technology, exit interviews were conducted with former students of the program who had either completed or dropped out of the program. To seek another perspective of student's use of technology, four teachers and the director of the program were interviewed.

Participant observation was conducted during classrooms instruction and online activities. We participated in classroom discussions, especially since the nature of teaching and learning in the program was more group-discussion oriented than traditional, teacher-led instruction. The program had an online component, where teachers and students interacted. Teachers used the online database to provide feedback to student work, answered student questions, and led class discussions about activities and events related to student projects. Students used the online database to interact with their teachers and coordinate their group projects. As participants, we participated in the discussions and observed students in their online activities and compared such activities to the face-to-face classroom setting.

Findings

The study found that technology was seen as an important that facilitated the student-centered learning approach used in the program. Students found technology as aiding collaborative and cooperative learning, participation, and providing easy accessibility to resources. They however mentioned that technology is an add-on to their learning, and for students with little experience or interest in technology, it can be challenging and discouraging in the learning process. Information from teachers and administrators revealed that technology supplemented their work. Teachers found in technology a tool that diversified their teaching styles, increased interaction with students and between students especially outside the classroom, and considered technology to be an important teaching aid. They emphasized that technology will be more effective if it is used together with face-to-face learning. They were also concerned about focusing on the significance of technology.

Technology has strong influence

Both students and teachers unanimously were of the opinion that technology played a strong role in influencing student projects. This included the creation and completion of projects. Students cited the Internet as providing access to vast and varied information when researching their projects. Students worked on real world projects, and indicated technology facilitated their work. For example, a group of students coordinated their work with a local community group in rural Ecuador using e-mail. For such students, they could not envision working on the project if they did not have access to e-mail facilities. Another group of students prepared documents about information dissemination to cotton farmers in rural Uzbekistan. According to the students, when reviewing literature and collecting information about the country, the library had a few, old books that were of little use. But the Internet was very helpful in studying the country, and the students felt that it was very invaluable in completing their project. In class presentations, students used Microsoft PowerPoint to present their work in a "clear, professional and well designed" format.

Provides flexibility

For many students, the flexibility that technology provided in working in groups was important. Students stated that they coordinated their group projects through the database, and this reduced the need and frequency for face-to-face meetings. According to the students, as working on the projects required group work, they indicated that without technology (online coordination), it would have been difficult to complete their projects on time. In addition, the use of the online database allowed long-distance learning for students who could not come to class. During the period of this study, a student who was involved in Sweden took a course and worked on projects with students on campus.

Learning outside the Classroom

As pointed out by the director, and supported by the teachers and students, use of technology allowed learning outside the "restricting walls" of the classroom. Students asked their teachers questions, and teachers provided answers to students questions more frequently than in the traditional classroom. Online postings during evenings and weekend revealed the need for interaction

BEST COPY AVAILABLE

between students and teachers outside class. Equating the online database with classroom activity and the e-mail interaction with individual student visits to teacher's offices, a student said technology allowed for teacher-students interaction "anytime, anywhere."

Students empowered

The use of technology changed the learning environment dynamics. Students became active participants in their learning. It increased students' interests in learning and provided students with diverse learning resources. A teacher noted that the relationship between teachers changed from a "vertical to horizontal" relationship. As students worked on real world problems where learning and knowledge is not confined to the syllabus, they developed problem solving and analytical skills, and technology played an important role in these. Students also felt that their virtual meetings reduced the "hassle" of booking rooms for meetings. With online meetings, they did not need any permission to meet. Many students said that the laptops gave them a "sense of power" where they could study anytime, anywhere.

Promotes independent learning

The nature of the program required students taking ownership of learning. Teachers and students said that the project-based learning involved students having more responsibility and engaging actively in the decision making process about their learning. Technology was an important component in the students overall control of their learning. Students felt confident and comfortable as the Internet provided them with "most of the information" they needed, thus limiting need for teachers help. Use of email made students increase interactions between themselves. A student would email another student on a weekend or evening if they need help with their work. These would not have been possible if they did not have access to emails. According to one student, searching the Internet is an "adventure", where learning by doing is common. Technology increased students' realization that they have potential to contribute to their learning.

Alternative Medium

Technology supplemented classroom teaching. Teachers found the limited classroom sessions were not adequate for covering work related to the real world projects students implemented. They indicated the online forum provided them with more time to guide their students in their projects. Students said the online forum was an alternative way of interacting with their teachers. But teachers and students emphasized that technology, whether online or in the classroom, supplemented teacher instruction, and would not replace such instruction.

Increased communication

Technology facilitated communication between teachers and students, and between students. Teachers communicated with students more. One of the teachers noted that he was able to meet his students online more often compared to students in his other classes where web or email use is not strong. Students felt that unlike the traditional teacher-student relations where students have to set up appointments with teachers, technology created an informal environment where students could send and receive messages from teachers any time whether it is weekend or late night. The administrator said that students emailed him without having to go through the bureaucracy of making appointment through the secretary. Some students said that when they wanted to have synchronous communication between themselves, they used instant messaging and chat services.

Improved learning

The vast resources that technology provided students with increased their level of learning. Students said that the Internet gave them access to information and materials from different sources through various media. Teachers said that the different instructional strategies such as the database, use of PowerPoint for presentation, the web and coordination using email, were helpful in teaching and most importantly in learning. Teachers said the different ways in which they interacted with students allayed the fears that one teaching environment or style may make their students find their lessons uninteresting. Students appreciated the different learning styles and settings as change is good for learning.

Team Study

Students had varied feelings about project-based learning. For those positive about teamwork, they cited the sharing of skills and resources. Teachers agreed with students who were positive about working in groups, arguing the quality of work produced by students had mainly been due to the different expertise students shared to implement projects. Narrating one example, Jessica said if in a "group there are students from visual communication working with students from history and computer science, such a combination can produce tremendous results." Even the less enthusiastic project-based learning students were in agreement with the rest of the participants in pointing out the benefits of division of work team study encouraged. But they had reservations about the difficulty in making groups members work on projects. To them, it was difficult to organize meetings, indicating personal conflict could damage project success, and there was a concern of "joy riders" taking advantage of other student's hard work.

In rebutting some students' concerns, teachers found technology to be a tool for dealing with some of the students concerns. According to the teachers, technology provided a means to monitor group activities, which in a face-to-face environment would have been difficult. Teachers said that as students posted their work to the database, they were able to know which students contributed to the group work. In addition, they argued conflict of scheduling was easily resolved if students coordinated their activities on the online forum.

Concerns about technology

Limited technology experience

Several students were of the opinion that the application of technology for instruction, whether online or in a classroom environment, should take into consideration student skills and preferences for the medium of instruction. Some students indicated that they did not have any experience in online learning when they first joined the program, and without any orientation or technology skills, were required to participate in online learning. They cited frustration during the first few weeks into the program and reported of students who dropped out of the program because of limited computer skills, and difficulty in adapting quickly to the use of the online database. There is the expectation that students in college "should be familiar" with programs like the web, email and online databases. Teachers did not provide any technology orientation to students, and students were left on their own to learn technology. Students did not have an alternative to the online database. Though the instructional style was geared to be student-

BEST COPY AVAILABLE

centered, making major decisions such as online learning did not go down well with some students, especially when it was a required medium for learning. Students voiced the concern that a general assumption was being made about the 'goodness" of technology. For students with limited technology experience, they found technology overwhelming and confusing.

Lack of privacy

Several students cited lack of privacy in using the online database. They said that teacher-student confidentiality was breached when they used the database to submit their individual assignments, and teachers provided evaluation of their work online, which was accessible to other class members. Teachers monitored student postings on the database, which some showing concern that teachers may prejudge them as they could be influenced by individual activities on the online forum. An interview with one student revealed reluctance by students to post their work online for fear of peer "intrusion" into their work and a preference for giving a hard copy of their work to the teacher in class.

Technology overemphasized

Students complained that teachers abdicated their responsibility of teaching students by encouraging students to use the Internet. Teachers encouraged students to use the online database when interacting with them. Students said that teachers were hiding behind the "veil of technology" and provided limited support in student research for projects. While students appreciated teacher's support when using the online medium, they indicated that too much emphasis on technology undermined the real concern for content. There was a strong use of the Internet for research. Students felt that they were more inclined to use online sources for guiding their project than teachers.

Limited learning

Online learning did not provide in-depth, synchronous interaction that student got from the classroom, face-to-face learning. Students said that the online learning was "casual" and "superficial". Teachers did not respond to student's queries on time. Teachers' responses to students were "short", "inadequate", "unclear" and "late". Because of the asynchronous nature of the database, follow-up interaction between students and teachers was limited. Immediate feedback was rare, if not non-existent. Many of the interviewees said that with the use of technology, learning appeared a far away activity to them. Students felt learning became detached from the personal and human dimension. Several students said that it was easier to interact with teachers in the classroom.

Affects collaboration

Students stated that while technology facilitated group coordination, it nevertheless undermined collaborative work by students. Some students argued that by posting their reports to the group database, it appeared they were doing their individual work with limited contacts with colleagues. Several students said they were not used to virtual meetings, and would have preferred face-to-face meeting of team members. The reduced human contact, because of the use of the database, lessened some student's belief that they were working with their peers on the same project. One student reported uneasiness in expressing his ideas using the database and pointed out he would have been more productive if he addressed his colleagues face-to-face.

Conclusion

The use of technology in this setting had a major impact on the project-based work of the students. While most viewed the use of technology as positive in supporting the mentoring of students "anytime, anywhere," others saw technology in a less positive light and as hindering their learning. The faculty at the GLC community was very positive about the impact of the use of technology in providing alternative ways of communicating information to students and encouraging " after hours" learning in a project-based learning environment.

(Re-)Designing an Educational Setting
Trails of Competency in an Open Learning Repository

Heidrun Allert, Christoph Richter
Learning Lab Lower Saxony, University of Hanover, Germany
{allert, richter}@learninglab.de

Abstract: This paper focusses on consulting services, which address the process of (re-) designing an educational setting. The educational setting is supported by technology. Consulting makes explicit requirements and needs, and also has to take into account implicit objectives and assumptions on learning. In order to face these needs we implemented trails of competency and expertise, which are designed along the concept of Communities of Practice, into the metadata-based Open Learning Repository. This repository allows the integration of diverse instructional models. Consulting at this stage focussed on transforming experts' tacit knowledge to explicit knowledge.

Motivation

Higher Education in the field of computer science is dominated by the instructional principle of expository teaching as well as cognitivism. At the same time departments of computer science and electrical engineering often manage projects which develop and implement technology which supports learning, such as systems of Computer Managed Instruction. Web-based learning repositories therefore often focus on the presentation of learning material (web based content presenting domain specific knowledge) and provide access to information units, often called learning objects. Concepts concentrate on how to structure and organize ^learning objects. Some standards for learning objects (LOM, 2001 e.g.) reflect this view on learning.

Forming the team of instructional design and theory-based evaluation at the Learning Lab Lower Saxony (http://www.learninglab.de), which acts as a common research facility for several universities, we offer consulting services in the field of 'innovative learning technologies'. In our work we realised that teachers in Higher Education often have implicit learning and teaching objectives and goals as well as assumptions on learning and the learners which they never make explicit and which they do not explicitly address in their courses. These objectives, goals and expectations often aim at competences rather than domain specific knowledge. Therefore we planned to integrate the idea of competency-based learning into the Open Learning Repository. Its metadata-based architecture is open to the integration of diverse instructional models by forming separate models: the domain model (modelling domain-specific semantic networks) and the instructional model (modelling instructional information such as structuring learning and cooperation processes) (Allert et al., 2002). The guiding question for integrating a new instructional idea was: *how to create a surplus or added value which facilitates a change in teaching and learning culture*. We did not want to simply map and reproduce conventional teaching scenarios to a web-based system. Also, we did not start to design and implement the system based on this learning principle, but started a process of (re-)designing an educational setting. Aiming at the process instead of the product in the beginning is responsible for the restructuring of the entire (social) context. We designed the context and asked the question of how to support this context by technology. We concentrated on making explicit learning and teaching objectives, which are implicit, and offered continuous consulting. Within this process a further instructional principle turned out to precisely meet the needs: the concept of Communities of Practice (CoP). Therefore the core element within the learning repository are trails of expertise, now. Experts are full members of scientific communities. Consulting at this stage concentrated on making tacit knowledge explicit.

Teacher's Requirements and Needs

The development of computer supported learning environments often aims at decontextualized solutions. Re-designing and restructuring an educational setting does require an approach which is contrary. Consequently starting from a concrete setting in order to elicit requirements guides the design of technology which then actually meets the needs. This approach essentially involves the teacher in the design process. We will sketch the steps of design in the following. The dates we added are just to draw a more vivid picture.

Step 1 (April 2002): Teachers and teaching staff often have implicit learning goals and assumptions on learning and the learners but do not address these in teaching. At this stage we focussed on making these implicit goals explicit and conceptualized them.

- We asked the teaching staff, what they demand of a successful student.
- We visited some sessions of the course in order to identify learning objectives which might implicitely have guided the design of the course. Within the course Artificial Intelligence, which we visited, we identified the training of a skill, which is relevant in scientific work. This skill was practiced in an isolated way and was not integrated into a whole and coherent process of scientific work. Another important element of the course was the integration of experts who were invited to give a talk.
- We wrote some scenarios in order to evaluate and communicate what we had observed. The teaching staff wrote scenarios of what they intended. Comparing our scenarios of observed objectives to the teachers scenarios of intended objectives, all of us realized that the lecture did not address the learning objectives that were intended implicitely and which the teaching staff themselves rated as valuable.

Step 2 (Mai 2002): The further design process was guided by scenario-based design. (Bødker & Christiansen, 1997 and Carroll, 2000)

- We started to write scenarios in order to describe an entire educational setting. We re-designed the existing setting and suggested to form a coherent structure: to allow students to understand the whole process of scientific work. We recommended to focus on competences instead of distributing content.
- The later scenarios focussed on how to support and facilitate the intended setting by technology.
- Scenarios were discussed within the design team as well as the teaching staff. (Allert & Richter, 2002)

Trails of Competency in an Open Learning Repository

Step 3 (Mai and June 2002): At this stage we actually designed the Open Learning Repository. Its core idea is providing trails of competency. Its instructional principle is the concept of CoP. Computer scientists within the design team drafted use-cases and prepared UML diagrams (Unified Modelling Language). We built a functional Mock-up as a prototype able to simulate the intended functionality. In order to actually make the system work we perfectly designed the interface, built HTML pages and integrated a basic workspace (BSCW) in order to enable cooperation (http://www.kbs.uni-hannover.de/~allert/olr/studie4/site/). Not implementing the complete metadata-based architecture (which is supposed to generate pages and links dynamically) enabled us to use and evaluate the system as soon as possible.

We identified two major competences which meet the teachers requirements and which we think are core for students of computer science and electrical engineering but also for many others: (a) The competence to manage and coordinate project-oriented teamwork. (b) The competence to plan and conduct scientific work.

Both of these competences are relevant in students' further academic as well as professional career. Many educational models organize learning in phases. Therefore we wondered which phases are relevant in scientific work as well as in project management. From a point of view of psychology both of these processes can be characterised as intentional and goal oriented activities. We decided to structure these activities according to activity theory (Miller et al., 1960 e.g.) and organized the activity into phases and different levels of granularity mentioned in activity theory (Volpert, 1999). The phases are meant to give orientation, structure student activities, and guide navigation.

Reflecting our concept we realised that we could not state universally valid concepts of scientific work. At this point we opted for the principle of CoP which in return provided us with further ideas for design and guided decisions: Not only research methods are diverse (heuristic, empiric as well as hermeneutic among others). Scientific communities are different from faculties. There are communities focussing on multidisciplinary topics such as technology&education. There are communities such *as Semantic Web, Digital Libraries, Peer to Peer, Robotics, Presence, Adaptive Hypermedia, Media Education (a very local community within Germany), Molecular Bioinformatics, Paleo Antropology* e.g.. Any of these communities share different routines, rules, and procedures such as: where and how and how often to publish results and share ideas (conferences, scientific magazines, or books; within months or years), the question on where and how to meet and communicate (at local workshops or at international conferences). Lave & Wenger (2001) view learning as situated activity. Its central characteristic is a process that they call *legitimate peripheral participation*. Learning means to allow students to move from peripheral participation to full membership. Scientists in our approach are full members or participants of the core group within a specific scientific community. Therefore expertise-trails are the central element within the learning repository: Members of specific communities (often members of several related communities) explain their strategies of how to state the state-of-the-art and identify relevant research question, how to conduct research and publish. They do not point to textbooks, but use examples of their own research work, point to relevant sessions at conferences, mailinglists, papers etc. They may explain the use of domain specific ontologies (such as Swebok, http://www.swebok.org) or the Text Encoding Initiative, as well as the use of metadata etc.. We provide several expertise-trails. Students may compare different strategies, procedures and routines within very different or slightly different communities. Students and student groups are enabled to identify their topic of interest and choose their favoured expert to ask him for supporting and consulting them and their work. Students then form instances of expertise-trails in order to share their work and learning progress. They collect documents, write reports and present their ideas and strategies towards an own project. Experts (full members of communities) communicate with students using the integrated workspace. These competency-based trails are called ScieCom: *Introduction to Scientific Communities* (http://www.kbs.uni-hannover.de/~allert/olr/studie4/site/trails/sciecom/sciecom.htm). For the project-based trails we asked experts who actually manage projects. One of these experts gained experience in virtual project management.

Figure 1: Screenshot of Trails of Expertise (Introduction to Scientific Communities)

Transforming Tacit Knowledge to Explicit Knowledge: Expertise Trails

Soon we realized that we face a typical problem of knowledge management (Sallis & Jones, 2002): we could not just ask an expert of how he usually does his work. In order to make the tacit knowledge explicit (and provide it in the expertise-trails) we developed the following strategy:

Step 3.1 (June 2002): We proposed the phases of activity theory and stated typical activities within each phase. We formed questions aiming at these activities in order to guide the interviews with experts.

Step 3.2 (June 2002): We explained the use of activity theory for structuring the activity of scientific work as well as the idea of CoP according to Lave & Wenger (Lave & Wenger, 2001) to the first expert. We interviewed him and taped the interview. He pointed out many concrete examples within his work.

Step 3.3 (June 2002): In transcribing the interview we realized that he did not carefully structure his answers along the proposed phases. We structured the interview along the phases and discussed the result with him.

Step 3.4 (June 2002 – open end): A continuing process is now under way. We intensely communicate with the expert about strategies as well as procedures within the target communities. For example: (a) Criteria for comments: the expert is asked to comment on students work and learning process. We asked him not to comment in an arbitrary manner, but to share criteria and make them explicit in the expertise trail: what does he think is a good research question? What are his criteria for commenting on students work in each phase? We also asked students to add criteria for comments they rate as relevant. While actually commenting students work this expert realised his own focus: an important aspect of a good research question does initiate communication between him and the student on the identified state-of-the-art and the student's research proposal. (b) Recently we received a call for student-volunteers at one of the relevant conferences by e-mail. We asked the expert to think about including a hint to this information. He agreed. As the HTML files providing his expertise trail are stored locally at the experts webspace and are simply linked by URL into the Open Learning Repository, the expert is able to change the contents of the trail any time.

This expertise-trail serves as model to further experts. The finished system will provide a library, consisting of, collections of expertise trails, finished students work, tasks, etc. Creating a new course means sampling relevant trails and entities.

Step 4 (July 2002): Students started to use the Open Learning Repository a few weeks ago. They are asked to state the state-of-the-art and identify relevant research questions. They share their work, provide documents and

BEST COPY AVAILABLE

describe their strategies. As scientific work does iterate in several stages, in which research questions are improved and detailed, the teacher does not focus on the perfect research question but on communication.
For evaluation within the process we asked them whether they rate the focussed competences as relevant for their futher academic as well as professional career.

Preliminary Results and Further Work

Organizing a process instead of purely focussing on the implementation of a software product, which might remain isolated, facilitated change in learning and teaching culture. Including the teacher in this process ensured that the re-design of the educational setting does meet his needs. He is motivated to go on with the process and constantly comes up with new ideas which he does integrate in the concept. He did not only change the course according to the new instructional principle, but the entire context: communication between teacher and students, communication between groups of students, procedures within exams e.g. Now, students may be motivated not only to work towards the end of the course but towards their thesis. There is a surplus associated with the Learning Repository: In addition to the acquirement of knowledge, learning processes as well as cooperation and communication is transparent to all participants. We succeeded in overcoming previous problems: tools were simply added to already existing settings, the educational context remained unchanged. Any teacher holds his own view and assumptions on learning. This reduces the scale of changes which are postulated by organizations or programs. The process of change must start from making explicit assumptions and views of all stakeholders within learning and teaching scenarios.
Implementing a prototype that only simulates the intended functionality allowed us to rapidly use and evaluate the learning environment. The Learning Lab Lower Saxony already designed an Open Learning Repository which is based on metadata. This OLR is open to diverse learning and teaching models. Now it definitely seems to be useful also to implement the new instructional model of competency-based learning and CoP.
As we work in the field of metadata and contribute to an initiative of standardisation in the field of Learning (DIN, the German Institute for Standardization) we concentrate on how to extend current standards. One idea is to extend Standards in order to be able to annotate learning environments which are designed along the idea of competency-based learning. We will form a set of metadata to annotate situated learning as well as competency-based learning in order to allow sharing and re-using conceptual structures. Explicitely modelling instructional principles and learning paradigms allows to share and re-use conceptual structures. This is different from initiatives which aim at forming standards which are instructional unspecific (LOM, 2001) or which form a pedagogical meta-model (EML, Koper, 2001).
Next steps: (a) Implementation of the instructional model within the metadata-based architecture of OLR. (b) Further evaluation during the course of Autum/Winter 2002. (c) Integration of further expertise-trails. Experts of related Communities as well as very different Communities. (d) Establish, sample and revise the OLR library, which will contain trails of expertise, a glossary, tasks, and students work.

Learning Objects on the Semantic Web
Explicitly Modelling Instructional Theories and Paradigms

Heidrun Allert, Christoph Richter, Wolfgang Nejdl
Learning Lab Lower Saxony, University of Hanover, Germany
{allert, richter, nejdl}@learninglab.de

Abstract: This paper presents a scenario which draws a vision of Learning Services on the Semantic Web. In this context we ask the question of 'What are Learning Objects?' and draft appropriate answers. We describe a datastructure which allows explicitly modelling diversity in the field of learning by including role-based attributes for Learning Objects.

Motivation

Various scenarios illustrate new possibilities enabled by the evolution of the Semantic Web, which is based on the assumption that each object on the web can be described appropriately and in a machine readable form. "*A new form of Web content that is meaningful to computers will unleash a revolution of new possibilities*" (Berners-Lee et al., 2001). But we currently recognize a lack of ideas and visions for the description of learning and teaching services within the Semantic Web. Up to now standards for metadata in the field of learning focus on search, exchange and re-use of learning material, often called content items, learning objects or training components (Cisco Systems Inc., 2000). Accordingly, training concepts focus on "*just in time access to training and information.*" (ibid.). Scenarios, which concentrate on how to structure and organize access to learning objects, are mirrored in concepts such as content packaging (SCORM, 2001).

Search, exchange and re-use of learning objects is a challenging intention, but only one aspect within a more comprehensive vision, based on how these learning objects are actually used in a learning context. We present a scenario which is guided by the idea of a mature learner and elaborate a theoretical model as well as a datastructure including role-based attributes for explicitly modelling specific learning theories and paradigms.

Scenario: *Learning Services within the Semantic Web*

Guiding principle of the scenario *Learning Services within the Semantic Web* is a learner, who does not only identifiy what he needs to learn right now (knowledge, skills, and competences) but also anticipates how he learns successfully (what conceptual/educational model meets his needs). Rautenstrauch (2001) explains: *Life-long learning will be a learners own decision (...) the learner is mature (...) he will identify and define his own needs and prefered ways of learning (...) he will learn to learn selforganized, self-determined, and independent from predetermined curricula and institutional forms of organization.* A scenario, which presents main visions of the Semantic Web and its services, written by Berners-Lee et al. (2001) inspired us to write the scenario of *Learning Services within the Semantic Web*:

–Steve is an employee at an insurance company. His boss asked him to assume the leadership of a group of seven people in the analysis department. He may spend a fixed amount of time and money on advanced training to prepare for this new assignment. Now, Steve is asked to draft a proposal on his further education. Steve reflects on this chance: obviously his boss trusts in his responsibility and planning skills regarding his further education. He is allowed to anticipate his own needs in both form and content. He realizes that he does not only have to reflect his requirements and needs regarding the content but also the way of learning, and the learning and teaching culture which is the most motivating to himself. The company does not run an own training department. Therefore he adjusts his agent to look for external courses offered. He anticipates the content he needs to learn: contract law, financial and personnel controlling [...] but also competences in planning, organization and communication. To define some more attributes he instructs his Semantic Web agent to trust the agent (and its set of attributes) of his colleague, who has often attended courses so far. But he still lacks attributes on the way of learning, learning and teaching culture.

After a short web search his agent informs him of an interesting consulting project on the internet, which offers learning services: The project provides some basic scenarios describing learning situations and context which are written like stories and are easy to understand. Each scenario reflects a specific model, theory or paradigm of learning and teaching. He decides for one that best meets his assumptions, opinions, and beliefs on learning he has drawn from previous learning experiences both successful and unfruitful. He is impressed: there is a scenario which reflects a learning model that confronts learners with complex real world cases and claims that must be handled within a group of learners. Great, collaboration and communication are key issues! He decides to choose two scenarios, called: "Communities of Practice" and "Situated Learning – Case-Based". The scenarios come with specific sets of metadata: the CoP-Profile and the SituatedLearning-Profile. Steve agrees to trust these profiles and adjusts his agent accordingly. His agent now searches for: specific content, a learning group to co-construct knowledge with, a tutor who acts as a coach, for suitable activities, and appropriate media-formats.

The agent comes up with a few suggestions: organizations which can offer what he looks for as well as a skill-management-like database offering tutors, coaches, experts and learning material. Steve sends his agent to the human resource department of his company, to synchronize its results with the companys list of accepted organizations. [...] A few month later Steve reflects on his latest learning experience, which was fruitful, and revises the adjustment of his agent: During the last weeks he has learned much about his own preferred way of learning and learningstyle.–

What is a Learning Object?

Based on this scenario we identify an exemplary list of general Learning Objects:

- Tutors offering services, support and facilities according to specific concepts and models (depending on different learning theories, learning paradigms, instructional principles)
- Experts with their specific area of expertise and competence
- Learning groups to carry out collaborative teamwork enabling collaborative knowledge construction.
- Peers to perform peer-tutoring
- Learning situations: Points of Cooperations - POCs (Wessner & Pfister, in preparation) e.g.
- Learning activities
- Learning material
- Media enabling certain activities (Videoconference, workspace)
- Conceptual structures (these structures reflect specific instructional models/paradigms/principles)
- Instructional ideas (the community of teachers of primary education do not only effectually exchange learning and teaching material but also ideas of how to use them – how to teach and support learning)
- Feedback

The important aspect about these learning objects is their character of not being unspecific with regard to learning theories, learning paradigms (such as cognitivism, constructivism) and instructional principles (such as PBL, case-based, CoP etc). A videoconferencing session is not yet a learning activity. It does neither constitute, characterise nor induce a learning activity. The appropriate learning activity is a session of collaborative learning using videoconferences within project-based learning e.g. . The activity might be even more specific: the mode of dyadic collaboration and the kind of structural support that influences collaborative knowledge construction (Fischer et al., 2000) characterises the activity. Another example: There is not a single concept of tutorial support, but diverse concepts, diverse roles and tasks of a tutor, depending on the design of the learning situation. The design of the learning situation is guided by different learning theories/paradigms, instructional principles. Any theory, paradigm and principle reflects specific assumptions on learning. The term "tutor" therefore does not yet imply a specific task or a specific mode of support. Within a setting of collaborative problem solving the tutorial concept of support might be totally different from a training session guided by the instructional principle of drill and practice.

Explicitly Modelling Diverse Learning Theories, Paradigms and Principles

The basic principle of the Semantic Web is to bring structure to meaningful content as well as the ability to process semantics by automated means (Berners-Lee, 2001). Meaning of information is decoded within context. But the learning sciences per se cannot provide an unequivocal context, only specific theories can serve as centre of references and as context for expressing and decoding meaning. This becomes clear for example with attributes like the LOM Category *Interactivity Level* (LOM, 2001), which is hard to understand and use appropriately, because interactivity within cognitivistic approaches is different from interactivity within constructivistic approaches. Standardization in the field of learning faces the diversity visualized in figure 1. Different approaches have been proposed to now. Initiatives like LOM (2001) aim at forming standards which are instructional unspecific while the Educational Modelling Language (Koper, 2001) forms a pedagogical meta-model. From the point of view of several approaches within the philosophy of science it is not possible to aim at being unspecific. Sets of metadata usually reflect specific learning paradigms and instructional principles (expository teaching e.g.).

In the field of learning we face valuable diversity. Standardization has to address and take into account different scenarios based on diverse requirements and assumptions on learning. The the context for standardization in Learning is well characterised by Lyotards comprehension of science which is explained by Beck as follows: There is need to emphasise in a postmodern manner the conflicting diversity of models, the competition of paradigms, and the impossibility of integrative and finally valid solutions. The failture of integrating theories is specified a characteristics of postmodernism (Beck, 1993). Standards that aim at instructional neutrality must fail from the point of view of the science of philosophy. They risk addressing a narrowed perspective on learning. Also the formation of a pedagogical meta-model (Koper, 2001) is not what we intend and view as a solution. We want to open the view on learning in standardization and propose an approach of *Instructional Roles* in Learning Metadata Standards, which supports the idea of explicitly modelling and annotating different paradigms, models and principles in learning. The concept of *Roles* we use is taken from the field of semantics and formal languages (Steimann, 2000). Steimann recommends to introduce the concept of *Roles* into object-oriented modelling in order to make possible dynamic modelling. In a previous paper we proposed the concept of *Instructional Roles* to specify educational attributes for different learning theories (Allert et al., 2002).

In this paper we present a simple datastructure which reflects the modelling of diverse theories, principles and paradigms. It also allows the mapping of different approaches and therefore the exchange and re-use across the boarder of diverse theories/paradigms/principles – a basic requirement for standardization. We do not propose sets of metadata for any available theory. But we suggest this datastructure in order to prestructure the field and allow communities of practice to suggest specific sets of metadata. As our group has expertise in the field of situated learning we currently work out a set which we plan to propose and bring into discussion soon.

Figure 1: Standardization in the field of learning is confronted with diversity.

A Simple Datastructure to Describe Learning Objects

Building on previous work in IEEE LOM and IMS, we have those categories which are unspecific and mainly meant to facilitate mapping, search and re-use of Learning Objects independent of their instructional context: General (cp. Dublin Core), Technical, Annotation, etc.. Additionally, we then have those categories which give information on educational/ instructional attributes of Learning Objects, modelled along specific theories/paradigms/principles and are called *Instructional Roles (IR)*. *IRs* allow explicitely modelling diversity, enable dynamic modelling, and serves as centres of reference. In order to allow mapping, search, exchange and re-use at this level as well, we present a common set-of categories. Each *IR* guides the set up of specific vocabulary within a category. As an example we contrast two *IRs*: *Expository* and *Situated* (Table 1). They have vocabulary in common, e.g.the *Tutor* is mentioned in both models. Only the specific *IR* defines the specific meaning of the term and serves as system of reference.

The categories and vocabulary presented here are very vague and not at all a final draft, they serve only to explain the structure of data. We currently contribute to the work at the German Institute for Standardization (DIN) which specifies these categories. The structure of data is on the one hand inspired by the Berliner Modell and the Hamburger Modell (Peterssen, 1994). These theories expose different fields of decisions within educational settings. Pawlowski brought the Berliner Modell into standardization activities (Pawlowski, 2001). On the other hand we introduced layers of abstraction which are exposed by Klafki (1993), and Merrill (2001) and formed the *Instructional Roles* (Allert et al., 2002).

Further Work

We currently work on the consulting services in the field of learning mentioned in the scenario: different scenarios (such as best practice scenarios) reflect specific instructional and learning theories, paradigms and principles. They come along with specific sets of metadata. The scenarios help to identify ones own needs in learning and teaching even if one lacks specific terms of the learning science. The scenarios also serve as specification and characterization of categories and vocabulary for those who use and for those who annotate Learning Objects.

Situated Citizen Photojournalism and a Look at Dilemmatic Thinking

Mike Ananny, Carol Strohecker
Media Lab Europe
Sugar House Lane, Bellevue, Dublin-8, Ireland

{ananny, stro}@media.mit.edu

Abstract: We present an approach to investigating the development of "dilemmatic thinking" in individuals and communities. To study this style of thinking we use a framework called Situated Citizen Journalism (SCJ) in which non-specialists ("citizens") work with professional photojournalists and learning technologists to create and critique images. The participants form a "community of journalistic practice." This paper describes the SCJ approach; the rationale for situating the investigation of dilemmatic thinking within the photojournalism practice; and a project currently in progress to investigate young people's dilemmatic thinking through photojournalism. We conclude with a number of research questions guiding the development of collaborative software to support SCJ.

Introduction

We are interested in dilemmas and how people think about them (Billig, 1988; Gilligan, 1982). That is, how do people create, share and revise opinions about everyday situations characterised by ambiguous and perhaps competing perspectives? We distinguish this kind of thinking from psychological investigations in which dilemmas or scenarios are presented as stimuli to evaluate problem-solving and decision-making strategies (Kahneman and Tversky, 2000). Our interest is in how these dilemmas arise, how individuals and communities think about and represent dilemmas and how contextual factors and learning environment designs affect the development of dilemmatic thinking.

Instead of creating controlled environments to simulate dilemmas and scenarios, we work with people to create tools and environments in which they can work with us to study their own dilemmatic thinking. We do this through the design and use of "objects to think with" (Papert, 1980). We work with people to create tools for capturing images and constructing opinions that they can then use in informal, everyday settings. Our objective is to study *in situ* dilemmatic thinking by letting people create, share, debate and revise opinions in ways that are personally and contextually meaningful.

As a guide for investigating this style of thinking and for designing these new technologies, we use an approach called Situated Citizen Journalism (SCJ). In this paper we present this approach and our early progress on a project to investigate children's dilemmatic thinking as they create photojournalistic images.

Situated Citizen Journalism

Situated Citizen Journalism (SCJ) is a kind of participatory journalism in which citizens, learning technologists and journalism practitioners collaborate to create technologies and stories. Our goal is to support non-specialists as they develop the tools and skills needed to uncover and share perspectives that we don't usually see in traditional, mainstream media. At the same time, we hope to learn how journalistic frameworks and digital technologies can combine to create new ways of constructing unique points of view. We do this in three ways: *collaborative tool design*, *skills sharing* and *broad dissemination*.

During *collaborative tool design*, citizens, learning technologists and journalism practitioners work together to create design specifications and early prototype of the technologies needed to support citizen journalism. During *skills sharing*, citizens conduct fieldwork (with the support of journalism practitioners and technologists) in which they use both traditional and custom tools to capture images they will use to create stories. During *broad* *dissemination*, citizens, journalism practitioners and technologists work together to edit, produce and exhibit their stories, carefully choosing the representation and medium most appropriate to the perspective they wish to present and the audience they wish to engage.

Photojournalism: A Dilemmatic Profession

We choose to narrow our approach to photojournalism for two reasons. First, photojournalism is an inherently dilemmatic practice: the "whole story" can never be told with a single image or even an entire photo essay. Second, we believe photojournalism offers a different kind of accessibility (compared to text -based journalism) for letting communities of people of different ages, backgrounds and literacy skills create and critique dilemmas. People are familiar with taking snap-shots and viewing images in a variety of media but they rarely practice complex skills associated with visual analysis. Photojournalism is a "low-threshold, high-ceiling" domain in which to study dilemmatic thinking.

The good photojournalist uses a number of technical and rhetorical techniques to create literal and conceptual frames that tell stories. At a shoot, she simultaneously judges lighting conditions and camera angles, considering complex relationships among focal lengths, shutter speeds and film types as events unfold around her. She also makes split-second decisions about other more subjective issues: what is the most "important" aspect of an unfolding story? What aspects of the story best lend themselves to an image? Who is the audience for the image and in what medium (*e.g.* newspaper, magazine, Internet) will it be published? How can what's happening outside the frame be represented? As the photojournalist shoots a scene, she is simultaneously documenting a scene and presenting a personal perspective.

The framing continues even after the shooting is over. An editor may choose to crop, resize or even alter a photojournalist's image[1]. The layout designer may juxtapose the photojournalist's image against another image or text that influences the photojournalist's intended story. Furthermore, the publication's perceived bias (deserved or not), the timing of the story in relation to other events and the particular demographic of the target audience can all influence the image's voice. (See Kobré 2000 for a general introduction to photojournalism.)

Although such a process may seem flawed and confusing, there is evidence to suggest that people benefit from interpreting the ambiguity of mainstream media. Participating in conversations about the news is thought to cause deliberations that lead to more "informed" citizens with more concrete opinions and to contribute to a mutual awareness of public opinion and community attitudes (De Boer and Velthuijsen, 2001). De Boer and Velthuijsen acknowledge the limitations of evaluating relationships with mass media through surveys and knowledge tests. However, a consistent finding in their *dependency-exposure-conversation* model is that people seem to use news stories as bases for conversations and that deliberation about news items helps people develop individual opinions and determine how these opinions are received in a community. We are interested in further investigating this interplay between mainstream media, individual opinion-formation and community identity, but we adopt a different methodology.

By situating the SCJ approach within photojournalism, we hope to extend the analytic thinking skills exercised as a media consumer to the dilemmatic thinking skills practised as a media creator. We are more interested in *how* people think about issues, instead of simply *what* people think about issues. Constructing and critiquing seemingly ambiguous opinions and dilemmas through images may reveal new learning processes and new ways of supporting personal expression.

The Situated Citizen Journalism Learning Community

The community within which the citizen journalist develops cannot be separated from the skills associated with "good" photojournalism. Indeed, the professional photojournalist struggling to capture a scene or perspective likely learned her craft through a combination of formal instruction, apprenticeship, quiet observation, reflection, experimentation with tools and techniques and many, many mistakes.

---

[1] Altering news images is controversial but not without precedent. See Jacobson (2002) for a pictorial review of the relationship between photojournalism, censorship and image ambiguity.

Our goal is to create an environment in which citizens and photojournalists can engage in professionally situated, apprenticeship-like learning relationships (Lave & Wenger, 1991; Rogoff, 1991). The learning environment is not a formal pedagogical space but an informal environment where individuals of different ages, socio-cultural backgrounds and technical expertise collaborate to create and critique personally meaningful images.

Since it is often not possible to have such diversity within a single co-located physical community, a central goal of Situated Citizen Journalism is to facilitate diverse learning relationships through collaborative technologies. The exact nature of such an on-line group's collaboration requirements is a function of the individual learning and dilemmatic thinking styles of those who comprise the learning community.

Our current work (and the project described below) centres on identifying these on-line SCJ community requirements by studying how individuals learn and work together in a physical SCJ setting.

Situated Citizen Journalism and Children's Dilemmatic Thinking

Our first Situated Citizen Journalism project is a work-in-progress with two phases. In the first phase (beginning mid-August 2002), two groups of children from Dublin, Ireland aged 11 to 14 complete one-week workshops in which they work with learning researchers and photojournalism professionals to capture, edit, critique and exhibit images using a variety of traditional and digital photographic tools. In the second phase (beginning October 2002), adult students at Loyalist College's photojournalism school in Canada and Irish children collaborate using custom-designed web software to critique and edit the images.

Phase One: Workshops

The workshop participants were recruited through The Ark, a Dublin-based arts and cultural centre for children. The participants for the first workshop are members of the general public who registered with The Ark's summer programme and the participants for the second workshop were selected from a Dublin neighbourhood labelled "disadvantaged" by the Irish government. Both workshops have the same general design.

At the beginning of the week, children build their own pinhole cameras and use them to shoot images. They then develop the images using traditional darkroom processes as a first introduction to photographic principals of optics and light. As the week progresses, children work with a Loyalist College photojournalism professor and two Loyalist college photojournalism students to design their own photojournalism assignments. They then shoot two assignments using more advanced traditional and digital cameras and critique their images and stories as a group. After iterating on different themes and photographic techniques, they edit the images using both traditional cropping techniques and digital image editing tools. They then prepare a final public exhibition consisting of both a traditional, physical show and an on-line presentation.

Phase Two: On-Line Collaboration

The on-line portion of the exhibit will be shown using custom web software and will serve as the basis for the extended collaboration throughout Fall 2002. During this phase of the project, the Canadian photojournalism students work with the Irish children using the web software. Together they critique and edit images with each individual bringing a variety of photojournalistic and editorial expertise. The goal for this phase is to support children's further exposure to the photojournalism editing process as they converse with students of a different age and from another culture who are themselves learning what it means to be a photojournalism editor.

The software is designed using the open-source Open Architecture Community System (OpenACS, 2002) on the Linux operating system. The OpenACS system is a tool-kit for building community-oriented web applications. It is composed entirely of open-source components: an AOL web server, a PostgreSQL database and a set of tcl scripts that offer customisable functions such as user authentication, discussion forums and chat spaces.

Research Questions

There are several research goals behind the design of the workshop and the structure of the web-based collaboration. They are categorized as: *tool development*, *collaborative critique* and *community of practice*:

Tool Development

How do children use and talk about different photojournalism tools (*e.g.* pinhole cameras, fixed focal length cameras, digital cameras, image scanners, digital editing tools, *etc.*)? What features might future digital image capture tools have? How can aspects of the photojournalist profession be modelled in these technologies?

Collaborative Critique

How do children represent and critique dilemmatic and ambiguous aspects of visual scenes? How does the design of their assignments and the images they shoot change in response to critique? How are critiques given differently before, during and after a shoot and how are they *received* and *interpreted* differently?

Community of Practice

How do photojournalism professionals introduce photojournalism to non-specialists and mentor their development? How is this relationship like an apprenticeship learning model? What collaborative tools are needed to support this learning relationship remotely? As the photojournalism students work with the Irish young people, how do they learn from one another and in what contexts do these "learning moves" happen?

Conclusion

In this paper we presented an approach for investigating dilemmatic thinking and our current research project on how children's dilemmatic thinking can be practiced with the support of a situated learning community and, eventually, collaborative software. Our interest is in using the inherently subjective and dilemmatic practice of journalism in general – and photojournalism specifically – to investigate how people create, share and revise opinions about everyday dilemmas by capturing and critiquing personally meaningful images.

Acknowledgements

Thanks to researchers at Media Lab Europe (especially the Everyday Learning group and Elisabeth Sylvan) for helpful comments on the general research project and this paper. Thanks also to the Dara Carroll, Bernadette Larkin, the team at The Ark in Dublin, Ireland and to Frank O'Connor from Loyalist College in Belleville, Canada and Sarah Falkner and Jeff Cooper for their help designing, organizing and conducting the workshops.

The Nature of Electronic International Project Development

Betsy Anderton
Department of Behavioral Studies and Educational Technology
University of South Alabama
United States
betsyanderton@worldnet.att.net

Abstract: This paper is a report on the findings of a grounded theory investigation of international collaboration over the Internet in which partners develop educational products. This study was conducted over a three-month period in the summer of 2002. In this small study, I attempt to identify strengths and barriers to the international and electronic components of Internet international communications. Ten participants with experience in international electronic project development from nine different countries were interviewed electronically. Their answers were coded and compiled. The findings from this study should help prepare pre-service teachers for cross-cultural interaction and project development using the Internet.

Introduction

Schools of education are beginning to realize the need to provide teachers with information communication technology (ICT) skills. In order to supply knowledge workers to governments, businesses, and social institutions, schools of education must provide new teachers in training with ICT skills both in and out of the traditional classroom. It should no longer be considered novel, but necessary that we provide teachers with the training, technology, and collaborative resources to use ICTs in their classrooms, both for management and teaching. Schools of teacher education hold the responsibility to create teachers that will in turn create environments that encourage constructive interaction with students and information.

Along with ICT skills, pre-service teachers also need skills in global interaction. As our world and the information we receive from it become increasingly more global, it is important that teachers encourage students to accurately understand their society as part of a larger world. Von Glasersfeld (1989) believes it is through the views of others that people begin to challenge their own ideas and philosophies enabling them to accept new methods for teaching and learning. At the Society for Information Technology in Teacher Education (SITE), Nikki Davis listed three reasons for making the integration of technology into education an international responsibility, (a) the context of education is becoming more global, (b) the Internet and other ICTs have increased access to education on a global level, and (c) teacher education can be enhanced by an international approach through increased reflection and the provision of stimulating contexts. Davis elaborated on these issues stating that the globalization of teacher education should be a response to industries need for leadership, innovation, and customer service provided by a new type of global savvy worker.

In response to the demands for a new type of learner, teacher, and curriculum, the Internet is increasingly becoming a medium of choice for the development of ICT skills and international collaboration. It is my belief that if we are to encourage pre-service teachers to work with other cultures using an electronic medium, we need to understand the barriers they will face so as to incorporate the needed educational and motivational strategies into teaching and assignments.

Furthermore, by more clearly understanding the strengths of the Internet and international collaboration, teachers can include the Internet in their pre-service teacher education curriculums with more assurance as to the merits of this relatively new learning tool. The benefits can likely be used as motivating factors for involving pre-service teachers in both ICT use and international collaboration on project development. In this study I attempt to illuminate some of the characteristics particular to international Internet project development and communication. I examined these two questions: (a) What is the nature of international electronic project development? (b) How can knowledge of the strengths and barriers to

BEST COPY AVAILABLE

international Internet project development enhance efforts to include electronic international developments for pre-service teachers in colleges of education?

Method

Participants

Participants were chosen in two ways: (a) by looking through publications and noting the authors, and (b) finding organizations that listed individuals involved in international affairs. Participants were teachers and faculty members from a total of nine different countries. The terms *participants* and *respondents* are used synonymously.

Apparatus

Five questions were electronically mailed to each participant. Questions were designed to discover strengths and weaknesses of international collaboration on educational projects, strengths and weaknesses of Internet collaboration and communication, and opinions on international collaboration and pre-service teacher motivation. Questions were piloted on two participants, evaluated and then redeveloped. The final questions can be seen below.

1. What are the strengths to international development of educational materials and projects?
2. What are the barriers or limitations to international development of educational materials and projects?
3. What are the strengths of using the Internet to collaborate and build/develop educational materials and projects?
4. What are the limitations and weaknesses of using the Internet to collaborate and build/develop educational materials and projects?
5. Please provide your opinion on what motivations could be used to encourage international collaboration by undergraduate education students (future teachers)?

Procedure

I began my study by selecting a purposeful sample of individuals. All individuals had experience using the Internet for international project development. Thus the participant's experiences would strengthen the quality and richness of their responses. I sent out 25 emails initially. The low return rate of 4 in the 25 caused me to reflect on both my process and my questions. I then redesigned my salutation and description of the project to include a sentence informing recipients of the value of their contribution to the study, as they were only one of ten individuals being studied. I also researched the individuals project development history so as to congratulate them on a specific accomplishment. I felt that this would create a bond of professionalism and respect. Once I sent this new set out, I found that my return rate increased to 6 of 10.

All communication was in English. Once interviews were returned, I read the responses and began coding them. I first based the codes on the five question areas and then developed subsets of these areas as themes emerged. This method provided me with an effective system by which to question respondents further.

Results

Question #1: Benefits of International Project Development

The responses to the benefits of international development of educational materials were rich and full of enthusiasm. Seven of the participants responded to this question. Below are the most common remarks regarding the benefits of international project development.

• Supports language skill development	7
• Promotes comparisons of lives and cultures	7
o Solving common problems	
o Positive attitude toward differences, tolerance	
• Increases student interaction with materials	3
• Increases variety of student interactions	3

• Increases student enthusiasm	3
• Provides more resources for management, methods, and materials	3
• Supports teacher collaboration	3

Question #2: Barriers to International Project Development

Eight participants responded to this question. Language was stated most often as a barrier to international project development. The following responses were most popular.

• Language	4
• Time	3
• Exam oriented nationally curriculums	2
• Variation in school years	2
• Time Zones	2

Other answers included: difficulty in continuing projects started by other teachers, frustrations with English as the language of choice, student introduction to nationalistic and superior attitudes, lack of curriculum resources, cultural barriers excluding language, and traditional or close minded educators.

Question #3: Strengths to Using the Internet for Collaboration

Eight participants responded to this question. The most beneficial strength of Internet collaboration was its support and promotion of active learning, and student motivation.

• Built in student motivation	4
• Supports active learning through real-time, relevant activities	3
• Supports teacher collaboration	3
• Provides of resources for teachers and students	3
• Supports interaction information communication technologies	3
• Provides immediate access to other cultures	3
• Improves communication skills	3
• Personalizes the learning experience	2

Lack of discriminating elements such as race, age, and gender and the decentralization of national curriculums were also listed as strengths to international Internet collaboration.

Question #4: Barriers to Using the Internet for Collaboration

Eight participants responded to this question. The greatest barrier found to Internet collaboration was skill level of educators.

• Skill level of educators	5
• Internet connection speed	4
• Lack of equipment in schools	3
• Skill level of students	2
• Diversity of resources of partner institutions	2

Lack of resources in student homes and expense of resource were also listed as barriers.

Question #5: Suggestions for Motivating Students

The final question was designed to gather information on motivational strategies that could be used to support international Internet collaboration in pre-service teacher programs. I can not be sure that each of the respondents fully understood the term I used to describe this group, "undergraduate education students (future teachers)" Knowing that education systems differ throughout the world, I attempted to phrase this term as clearly as possible. Four individuals responded to this question. Some suggestions included use of international listservs providing opportunities for relationship building and networking, required online project development across borders, and provide paths by which they could meet leaders in the field and possibly help with projects.

Creating and promoting internship opportunities for students was listed as an additional way to involve pre-service teachers in international endeavors. One respondent finished her interview with these words, "The experimental spirits and the practical need are among the most important factors. As a teacher-to-be, they are self-encouraged to be innovative. Once they decide on exploring the world, they are delighted to create more opportunity to collaborate with others." So, perhaps we can imply that we need to send education students into the world with a certain spirit as well as a tool kit of technical and pedagogical skills.

Discussion

Regarding the use of this study to pre-service teacher education, I can only offer suggestions. Professors in colleges of education can make valuable use of the Internet as a tool for pre-service teacher education project development. Not only are teachers using the tool to collaborate, this tool has built in motivational factors that encourage Internet student collaboration. Such factors include immediate feedback, perspective sharing, opportunities to meet people from other countries, foreign language acquisition, and access to adaptable lessons and projects. However, students need to be versed in appropriate cultural behavior in order to work optimally with international peers. Communication must be clear and students must understand when to ask for clarification. Students from English speaking countries must value the efforts of their colleagues who do not speak English as a first language. This understanding will hopefully be passed on to their future pupils. Schools wishing to use the Internet for international project development need to have reliable and speedy Internet connections available for students to use. International electronic products should be planned carefully so as to fit into the year and curriculum. If projects are to be continued goals and project guidelines should be clearly communicated to follow-up teachers. Furthermore, project partners should communicate their motives for project participation.

There were several problem areas in my study, which I would like the reader to be aware of. First of all, response was initially low. I feel there were two reasons for this. First, I sent the email from an unprofessional hotmail address, which might have made my study appear less legitimate. Second, my first set of emails did not specify the limited number of individuals I was attempting to contact. Perhaps this lessoned prospective respondents motivation to return the questions. My second attempt in which I sent only ten emails and took efforts to inform the respondents received a greater response rate.

Internet interviewing is not a timely process. For those participants that responded, the delay averaged four-days between the time the message was sent and the time a response was received. Not knowing the preferred name of individuals also proved to be a hindrance to communication. I feel that although I received lengthy responses, it was hard to develop a relationship as I might have done in a face-to-face interview.

I agree with respondents that language is indeed a barrier and should not be overlooked. It is very important to pilot questions with a variety of nationalities before attempting to collect data. For example, my pilot test revealed various interpretations for the word "graduate student". I had several peers review my questions for clarity, but cultural interpretations were still an issue. Just as my questions could have been misunderstood, there may be some responses that I interpreted incorrectly.

Abstract: The aim purpose of this paper is to show a framework for elaboration and management of pedagogical contents used in distance, resource-based e-learning. The present article is based in current research being conducted at University Cruzeiro do Sul in Center of Distance Education (UNICSUL-NEAD) , Sao Paulo, Brazil, where the WEL Project (Web Engineering for Learning) is under development. The main goals of this research is to develop pedagogical content and generic tools, like simulations and assessment methods, for Web-based learning over the context of Computer Sciences and Information Systems undergraduate courses. The foundations for this project are the use of regular concepts of usability, reusability, , functionality, reliability, efficiency, maintainability and scalability over an implementation of learning objects, whose concept is recent but promising. Therefore, the framework here presented can be used on massive distance learning projects in formal and informal educational levels. The results of applying such framework over an undergraduate Information Systems course are reported.

Introduction

The use of Internet/Web for educational purposes has been discussed in several researches last years (Abbey 2000, Aggarwal 2000, Ryan et al. 2000). Experiences in the use of Web-based technologies have been applied in several segments of Teaching-Learning Process showing results that have contributed for a more efficient use of these technologies in the educational process. The Computer Sciences and Information Technologies areas are accomplishing a wide range of studies about the effectiveness in using Internet/Web as a learning and communication tool (Gal-Ezer & Lupo 2002). Such areas are directly concerned with research and development of ICTs (Information and Communication Technologies), and there is a large interest about the use of these technologies in educational programs. It is not possible to assert peremptorily -and in an unequivocal way- that the use of ICTs leads to a more efficient, better learning. However, as their use is increasingly becoming inserted into learning's social context, on schools or even at work, there is a need for more studies on this area, applying and analyzing the use of these technologies on the educational environment in order to move forward to a mode tailored use of ICTs on the Teaching-Learning Process (MacCormack & Jones 1998).

Recent advances in Web Engineering (Olsina 1999, Pressmann 2001, Nielsen 2000), mixed with the concept of Learning Objects (Wiley 2002) have crucial importance for developing a web-based course content that follows six basic standards: usability, functionality, reusability, reliability, efficiency and scalability. In this context, the WEL Project (Web Engineering for Learning), that is being conducted at Center of Distance Learning in University Cruzeiro do Sul, at Sao Paulo, Brazil, has as its main goal to research a framework for the development and management of pedagogical content for e-Learning programs, as well as to investigate what methodologies and tools can be used in order to reach such a goal. Thus, the whole research is based on Web Engineering basic principles, making use of the modern concept of Learning Objects applied to resource-based distance learning systems, whose content is in domain of Computer Sciences and Information Systems areas. However, the proposed framework can be used in several other areas, in order to manage massive courses in higher education. As this framework is well suited for educational aims, its use demonstrates a severe reduction of development efforts, so having a very positive impact on the cost/benefice ratio.

Our study was conducted on a course offered in the half-presence modality. All students that joined up this experience were Information Systems undergraduate classes. The results of such a research are shown here.

The Basic Foundations of the Framework

A working definition for the term "Learning Objects" was given by IEEE (Institute of Electrical and Electronics Engineers) Learning Technology Standards Committee (LTSC). According to that definition, Learning Objects mean any entity, digital or non-digital, that can be used, reused or referenced during technology-supported learning processes, including computer-based training systems, interactive learning environments, intelligent computer aided instruction systems, distance learning systems, and collaborative learning systems.

The Learning Objects concept is a starting point to the definition of standards for development of online learning contents, tools and assessment tools. As a consequence, we gain competitiveness to dispute into corporate e-learning market, in addition to more efficiency and flexibility in developing resource-based distance learning content for higher education (Whalen & Wright 2000). These standards converge to the Web Engineering specifications (Olsina 1999, Pressmann 2001), interface design theory (Shneiderman 1998) and the object-oriented paradigm (Booch, Rumbaugh & Jacobson 2000).

To build a high quality, efficient web-based content is a very expensive, time-consuming task. At first sight, content development include a wide range of tasks, like instructional design, multimedia design, text production, as well audio, motion video, graphics and photos conversion to machine-readable formats. In addition to these tasks, we have also other ones, like course authoring, software development, content integration and testing, modification/adjustment, training; and so. The cost analysis for asynchronous web-based course cases studies presented by Whalen (2000) show an average of 1,321 hours of content development for a two-day course in the context of web-based training in a corporate sector. The time for developing a synchronous course is pointed to be 89% fewer or 144 development hours (Whalen & Wright 2000). The convergence between the concepts of web engineering and learning objects in the context of higher education content development of didactical content leads to a optimization of the process, so that it allows the massive use of ICTs. Therefore, this background also allows the purpose of an effective framework for web-based course content development. Such background is structured in a n-tiered architecture which can be reused in several contexts than educational ones.

The (Figure 1) shows a Unified Modeling Language (UML) Use-Cases Diagram (Booch, Rumbaugh & Jacobson 2000) that depicts the main roles played by two actors – the Teacher/Expert, mainly responsible for the Instructional Design phase (Bergi 2000 in Abbey), when the content to be modeled is related to the expected goals of the teaching-learning process, and it is also the moment when all strategies that will be applied in such process are defined. In addition to that, to this actor is also assigned the responsibility of developing the content itself, and test its implementation, which is done by another actor, here called WebEngineer that has to model and implement the content previously planned by the Teacher/Expert.

context, "Static Content" means all that content that is drafted by Teacher/Expert during Content Development phase, after modeled and implemented by WebEngineer. This implementation is done basically through webpages, in general elaborated over DHTML, Javascript and other technologies under the W3C (Word Wide Web Consortium) standards. It is important to note that most of the components that are shown in (Figure 3) are implemented in (Figure 2).

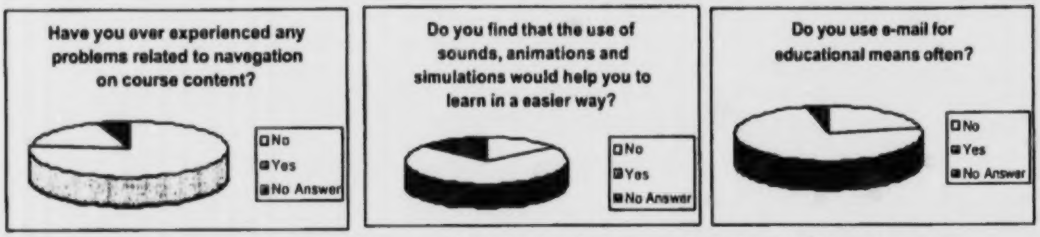
Preliminary Results

The implementation of the framework was made using the WebCT learning environment. It is important to emphasize that such framework can be used in several ways than educational ones, independently of the virtual learning environments over which is implemented. The application of this framework results in a modeling content (Pressman 2001, Nielsen 2000 Lynch & Horton 1999). This modeling content was applied in a first undergraduate course in Information Systems area, and a larger range of experiences are being drawn from this one, based on a survey that has been realized in order to evaluate de pedagogical impact of the framework over students.

Questions about navigational issues on the proposed modeling content show that 77% of students had no problem in navigation, against 18% that have had. It was asked the students' opinion about the utilization of multimedia resources like sounds, animations and simulations in the learning process. The answers for this question showed that 70% of students believe that these resources could help in learning process, 16% of them found that such resources would not help them to learn in an easier way, and 14% of them have no opinion about this. The students also declared that 74% of them use regularly e-mail for educational purposes against 22% that do not. These results are depicted in (Figures 4a, 4b and 4c):



Figures 4a, 4b, 4c: Questions proposed in a survey for evaluating the framework's pedagogical impact, as well as the use of ICTs on educational process.

Conclusions

The results of this research shows that the implementation of any project on distance learning in higher education must follow a straightforward, well-coordinated pattern on planning, modeling and developing its content, in order to reach students' expectancies and requirements. At this point, the need for a framework as proposed in this paper appears. The proposed framework allowed a drastic reduction of efforts on content building, and its use showed adaptive to the specific needs of each course planned after this.

The intrinsic problems related to the course subject itself had no change if faced to previous experiences without the use of ICTs. However, we could observe a greater motivation from the students, perhaps by the fact of using a friendly environment to study some subject, whose content were available whenever and from wherever. Other point that must be emphasized is the growing of peer-to-peer contact, among the students themselves, and among them and the teacher. We believe that fact is a trigger for a crescent motivation, consequently a breaking some of the uncountable barriers that separate learners from learning.

Acknowledgements

The authors acknowledge University Cruzeiro do Sul by the financial support for this research. We would like to thank Prof. Dr. Jaime Sandro da Veiga for his help on scientific discussions about resource-based learning.

Evaluation of web based communication and cooperation in a course in teacher education at a German University

Most of the universities have established some kind of e-Learning courses to support virtual learning. Often they use web based software platforms like WebCT or Blackboard. The experiences with such forms of learning are very different. Some are very enthusiastic; others are very sceptical about such platforms. Teaching and learning with new media is a great challenge for teaching at university, because to use the technique in a proper way needs some important prerequisites. For example the handling of the platforms must be easy for everybody, and the students must have the ability to use computer and internet.

To work with e-Learning software platforms there are different options: one is information, one is communication, and one is cooperation. For communication there are synchronic and asynchronic forms. Synchronic communication forms are for example chat and instant messenger services. Asynchronic forms are for example e-Mail and Discussion Boards. For cooperation or collaboration one can use file transfer function or whiteboards.

There are several reasons why students have problems in using such platforms. One could be a lack of understanding; one could be a lack of experiences. In a study at the university of Hamburg teacher students which attend a course on 'virtual school' where asked to use an e-learning platform for information, communication and cooperation during their group work. The groups had the task to evaluate websites for teachers in different subjects, to analyse learning software for young students, and to develop classroom projects from a constructivist point of view. To work on these tasks they have to use e-Learning software platform Blackboard. Blackboard is one of the biggest players in the e-Learning market and offers the user to create course sites in which students can enrol. The system offers a wide range of possibilities. One can make announcements, provide course documents, and they are possibilities to send emails, to chat or to use discussion boards, e.g. After a period of eight weeks of group work the students had to present the projects on the course website for discussion. The course was attended by 80 students of a course for teacher education. Most of the students were freshmen, two third were female.

A questionnaire was used to evaluate the experiences by using Blackboard. The questionnaire has several dimensions which focus to different aspects. One aspect has been the ability of the students to use computer and internet which was called media competence. Another aspects focus on the students' experiences in using Blackboard.

The results show that 20% of the students have had technical problems to use Blackboard in a proper way. One of these problems has been a slow modem for internet access. Most of them used Blackboard only for information and communication but not for cooperation. They preferred to meet 'offline' to work on their tasks. Only one group of twenty-five groups used a discussion board, none of them the chat room or the whiteboard. Two third of the students used Blackboard up to ten times, one third less than five times. Most of the students 'forgot' to read some of the course documents. Asked which of the options of Blackboard they find useful and which they really used, most of them find that announcements and emails to the instructor are very useful and has been used too. But there is a big gap for the more cooperative options of Blackboard. Half the students answered that chat and discussion boards are very useful, but only a few of them used them. More than one third of the students called working with Blackboard very awkward. Further results are presented.

One of the conclusions of the evaluation study is that it is very necessary to give the students an extensive introduction in working with e-Learning software platforms. And another conclusion is that the pedagogical sense of using such platforms must fit the communication and cooperation demands of students.

Evaluating distributed learning

Isabel Azevedo, Constantino Martins, Carlos Vaz de Carvalho
Instituto Superior de Engenharia do Porto (ISEP) - Portugal
iazevedo@dei.isep.ipp.pt

Ligia Maria Ribeiro
Faculdade de Engenharia da Universidade do Porto (FEUP) - Portugal

Abstract: The evaluation of distributed learning, in a systematic and a rigorous way, is a mandatory process to assure its quality and efficiency. At the Engineering Institute of Porto (ISEP), distributed learning has been adopted by an increasing number of disciplines, either as complement to f2f classes or as the main delivery methodology. This led us to design and propose an evaluation methodology to assess the results of these actions. We are currently validating the methodology, using a course from the Computer Science BSc. Once subject to other courses, the methodology can easily be extended to other higher education distributed learning courses.

Background

Evaluation is the systematic determination of merit or importance (Scriven, 1999) that allows problems identification, classifications and comparisons to be done. This activity is essential to assure the quality in education (Gilroy, 2001), benefiting all the stakeholders in the process. Evaluation is especially relevant to any form of distance learning, including distributed learning, because the need to establish this form of education as valid is still felt ([Mann, 1998] [Williamson, 2000]).

According to Moore (1999), an adequate accompanying and an effective evaluation can also contribute significantly to distance education courses success, but only a small number of institutions have recognized that these courses success depends on so many related parts and that the failure of one of them can compromise the role initiative (Alexander, 2001).

For instance, little attention is given to the learning processes in distance education courses. The students' frustrations aren't recognized in many courses (Hara, 1999) where only the students who did not drop out answer final evaluation questionnaires. Perhaps this lack of interest can be the main reason for the high number of students that can't finish their distance education courses. According to Evans (2000), 30 to 50% of distance education courses' students drop out their courses before the end, independently of the technologies that were used, but Alves (2001) presents a figure of 80% in some courses. These values suggest that something has to be reconsidered since the beginning of any course. The courses development cannot be the only aspect that matters in distance education.

In summary, evaluation is not an activity to be carried only in the final of a course, because at this time it is too late to do changes for the course success. Clark (1989) defends that the evaluation specialists have to be effectively involved in the courses implementation as soon as possible. Even if the evaluation process is very time-consuming and even if educational tasks are not often considered for teachers' professional progress in higher education schools.

Evaluation Methodology Design

To design the evaluation methodology we followed four evaluation phases, based on Scriven (1980):
